Introduction

1.1 About this manual

This manual is intended for persons responsible for configuring and managing video analysis software from Bosch. This manual provides background information about video analysis and describes how to configure the software.

1.2 Conventions in this document

The following symbols and notations are used to draw attention to special situations:

Notice!
This symbol indicates special features and provides tips and information for easier, more convenient use of the software.

Terms that you can find in the program, such as menu options, commands or text in the user interface, are written in bold.

1.3 Accessing the Help

Use the Help within the program. This Help provides background information about video analysis and describes how to configure the software.

To access the Help in Configuration Manager:
1. Press F1.
   or On the Help menu, click the help entry.
   The dialog box for the Help is displayed.
2. If the pane to the left is not visible, click the Show button.
3. For more information, click the topics in the Help.

To access the Help in web browser:
1. Press F1. The Help window is displayed.
2. For more information, click the topics in the Help.

Notice!
Open the Help in the program to obtain information about using the Help, for example, searching, finding and printing information.

1.4 Additional documentation

Documentation and software for Bosch Security Systems products can be found in the online product catalogue as follows:
- Open any browser > enter www.boschsecurity.com > select your region and your country
  > start a search for your product > select the product in the search results to show the existing files.
System overview

General information about video content analysis (VCA)

Video content analysis is the process of automatically analyzing video images to alarm on predefined events like the detection of moving objects in the monitored area or tampering with the camera. It can also be used to gather statistics about the detected objects.

Depending on the camera type the following VCA algorithm are available in Bosch cameras:

- **Intelligent Video Analytics:**
  Mission-critical, long-distance intrusion detection in extreme weather conditions.
  Detection and tracking of moving objects.
  (see Intelligent Video Analytics, page 10)

- **Intelligent Video Analytics Flow:**
  Basic motion detection of cells in a grid with velocity and direction. Used for counter flow detection in crowds.
  (see Intelligent Video Analytics, page 10)

- **Essential Video Analytics:**
  Reliable video analytics for small and medium businesses, large retail stores, commercial buildings, and warehouses. Detection and tracking of moving objects.
  (see Essential Video Analytics, page 11)

- **MOTION+**:
  Basic change detection of cells in a grid. Can be used to trigger recordings.
  (see MOTION+, page 19)

- **Tamper detection**:
  Detects camera occlusion, turning away from the monitored scene, extreme lighting conditions and basic idle / removed object detection.
  (see Tamper detection, page 20)

Metadata

Metadata are the collected information from video content analysis algorithms. For Essential Video Analytics and Intelligent Video Analytics this includes all information about detected and tracked objects in the monitored area as follows:

- Alarm and counting events
- Object position and trajectory
  - In the image (2D)
  - Geolocation / ground plane coordinates (3D)
- Object shape
  - Bounding box
  - Outline
- Object properties
  - Object classification (Upright persons, Cars, Trucks, Bikes)
  - Object size (in the image and in reality)
  - Object speed and orientation
  - Object color histogram
  - Object ID

For MOTION+, the amount of change for each cell in the MOTION+ grid is included in the metadata. For Intelligent Video Analytics Flow, the metadata describe the computed motion direction.
Example:
Separate video and metadata streams. The metadata stream includes the outline of the detected car.

Intelligence-at-the-edge concept
The video analytics software is available in Bosch IP cameras. This intelligence-at-the-edge concept allows a decision on which videos are captured based on video content analysis (VCA). Bandwidth and storage can be reduced by recording alarm situations only or by selecting the best video encoding quality and frame rates exclusively for alarms. Alarm conditions can be signaled by a relay output on the unit or an alarm connection, to stream video to a decoder or video management system. Alarms can also be transmitted to a video management system to start extended alarm scenarios. As well as creating alarms, the software produces metadata that describes the content of the analyzed scene. This metadata is sent over the network, and may also be recorded, together with the video stream.

Forensic Search
The recorded metadata can be used for a full forensic search where the rules can be changed even after the fact within Bosch Video Management System (Bosch VMS) or Video Client. New tasks can be defined and adapted for each search, and the recorded metadata is then scanned and evaluated accordingly. Forensic Search is very time efficient and can scan a huge recording database for events within seconds.
Notice!
You cannot change the metadata after they are generated. For Forensic Search, any task based on evaluating the metadata can be used, modified and optimized. However, the metadata itself cannot be changed anymore.

Configuration complexity on demand
The video analytics software automatically alarms on any object in the scene. More complex setups are supported as well: up to 8 independent tasks can be set up in the GUI, and the alarm objects for each task can be restricted according to their properties. Camera calibration can be added for perspective correction and to obtain object properties in metric or imperial systems. A wizard is available to support the calibration by marking lines and angles in the scene. A task script editor is available for fine tuning and combining predefined tasks, and additional 8 tasks can be set up there.

Intuitive graphical user interface
Setup is available via device web page as well as via Configuration Manager. A wizard-based graphical user interface guides through the configuration. All configuration options are visualized exemplarily as overlays for feedback and can directly be manipulated for intuitive configuration.

When movement is detected, the object is outlined in yellow on the display and its motion is displayed as a green trajectory. If an object and its motion match the rule conditions defined for one of the detector tasks, an alarm is created and the object outlines are switched to red. Additionally, an idle object is marked with an [I] and a removed object with an [X].

VCA quality
The quality of video content analysis depends heavily on environmental condition, for example:
- Visibility conditions like day, night, fog or occluding objects
- Cameras on poles shaking due to wind
- Vegetation moving in the wind
- Reflections and shadows

For further information, refer to the complete limitations for each provided video content analysis method.

VCA algorithms, features and limitations

3.1 Intelligent and Essential Video Analytics

Intelligent Video Analytics and Essential Video Analytics detect moving objects and track them over time. Many alarm and statistic tasks are available to analyze the motion of the objects in the monitored scene including location, direction and speed as well as their properties like size, speed, type and color.

Intelligent Video Analytics differs from Essential Video Analytics that the object detection and tracking algorithm of Intelligent Video Analytics is more advanced. This results in higher robustness to challenging weather conditions, shaking cameras, water in the background, and larger detection ranges.

3.1.1 Intelligent Video Analytics

Intelligent Video Analytics 6.30 by Bosch is the guard-assistant system of choice when you need mission-critical, long-distance intrusion detection in extreme weather conditions or other high-performance video analytics.

The software system is state-of-the-art intelligent video analytics that reliably detects, tracks, and analyzes moving objects while suppressing unwanted alarms from spurious sources in the image.

Intelligent Video Analytics adapts to difficult conditions like changes in lighting or environment such as rain, snow, clouds, and leaves blowing in the wind. It also compensates automatically for camera shaking.

Advanced tasks like multiple line crossing, loitering, crowd density estimation, and people counting are available. Object filter based on size, speed, direction, aspect ratio, and color can be defined.

For calibrated cameras, the software automatically distinguishes between the object types upright person, car, bike, and truck. And with version 6.30 the detection of objects at double the distance of version 6.10 is now available.

It allows you to record all of the object information and change the rules even after the fact for fully configurable forensic search.

Use cases

Intelligent Video Analytics is suitable for mission-critical applications and delivers extremely reliable results even under severe environmental conditions.

Intelligent Video Analytics covers the following use cases, for example:

- Perimeter protection:
  - Critical infrastructure
  - Airports and industries
  - Government buildings
  - Jails
  - Border patrol
- Harbor, canal and coast surveillance
- Traffic monitoring:
  - Enforce no-parking zones
  - Wrong-way detection
  - Monitor road side for broken cars
  - Traffic counts
- Protection of valuable items (alarm on touch or removal of museum exhibits)
- People counting
- Occupancy, queue and crowd detection
Dedicated tracking modes
Intelligent Video Analytics 6.30 includes dedicated tracking modes optimized for the following tasks:
- Intrusion detection
- Indoor people counting
- Asset protection (don’t touch!)
- Tracking of ships

Alarm and statistic tasks
The following alarm and statistic tasks are available:
- Detect objects within, entering, or leaving an area
- Detect multiple line crossing from single line up to 3 lines combined in a logical row
- Detect objects traversing a route
- Detect loitering in an area related to radius and time
- Detect objects which are idle for a predefined time span
- Detect removed objects
- Detect objects who’s properties such as size, speed, direction, and aspect ratio change within a configured time span according to specification (for example something falling down)
- Count objects crossing a virtual line
- Count objects within an area and alarm if a predefined limit is reached
- Detect a certain crowd level in a predefined field
- Detect specified motion direction and speed even in crowds (for example a person moving the wrong way in a one-way gate)
- Detect objects that move contrary to the motion of all other objects in the scene, even in crowds
- Take snapshots of frontal faces
- Combine tasks using scripts

Filters
To enhance robustness, the software can be configured to ignore specified image areas and small objects. For calibrated cameras, the software automatically distinguishes between upright persons, bikes, cars, and trucks. Furthermore, object size, speed, two-way direction, aspect ratio, and color filters can be used in any combination to create specific detection rules for exactly the objects you are looking for. Statistics on object properties are stored and can be displayed for fine tuning the object filters. Object properties can also be defined by selecting an appropriately similar object in the video.

3.1.2 Essential Video Analytics
Essential Video Analytics 6.30 by Bosch is the system of choice when you need reliable video analytics for small and medium business, large retail stores, commercial buildings, and warehouses.

The software system reliably detects, tracks, and analyzes moving objects while suppressing unwanted alarms from spurious sources in the image.

Advanced tasks like multiple line crossing, route following, loitering, idle and removed object detection, crowd density estimation, and overhead people counting are available. Object filter based on size, speed, direction, aspect ratio, and color can be defined.

For calibrated cameras, the software automatically distinguishes between the object types upright person, car, bike, and truck. It allows you to record all of the object information and change the rules even after the fact for fully configurable forensic search.
Use cases
Essential Video Analytics is suitable for small and medium companies, large retail stores, commercial buildings and warehouses to cover the following use cases:
- Detecting (indoor) intrusion for smaller environments
- Detecting queues and crowds
- Enforcing health and safety regulations (including the enforcement of no-parking zones and the detection of blocked emergency exits)
- Business analytics (including people counting, queuing and crowd density information)

Dedicated tracking modes
Essential Video Analytics 6.30 includes dedicated tracking modes optimized for the following tasks:
- Intrusion detection
- Indoor people counting
- Asset protection (don’t touch!)

Alarm and statistic tasks
The following alarm and statistic tasks are available:
- Detect objects within, entering, or leaving an area
- Detect multiple line crossing from single line up to 3 lines combined in a logical row
- Detect objects traversing a route
- Detect loitering in an area related to radius and time
- Detect objects which are idle for a predefined time span
- Detect removed objects
- Detect objects who’s properties such as size, speed, direction, and aspect ratio change within a configured time span according to specification (for example something falling down)
- Count objects crossing a virtual line
- Count objects within an area and alarm if a predefined limit is reached
- Detect a certain crowd level in a predefined field
- Combine tasks using scripts

Filters
To enhance robustness, the software can be configured to ignore specified image areas and small objects. For calibrated cameras, the software automatically distinguishes between upright persons, bikes, cars, and trucks. Furthermore, object size, speed, two-way direction, aspect ratio, and color filters can be used in any combination to create specific detection rules for exactly the objects you are looking for. Statistics on object properties are stored and can be displayed for fine tuning the object filters. Object properties can also be defined by selecting an appropriately similar object in the video.

3.1.3 Feature overview and comparison

3.1.4 Limitations Intelligent and Essential Video Analytics

This chapter describes limitations you should be aware of when using Intelligent Video Analytics or Essential Video Analytics. Though Intelligent Video Analytics is much more robust in many cases and makes much less errors than Essential Video Analytics, the root causes for potential errors are still shared with Essential Video Analytics and therefore stated here summarily for both algorithms.

Notice!
In case of doubt use the Intelligent Video Analytics algorithm.

Limitations of object tracking:
(Intelligent Video Analytics / Essential Video Analytics)
- Due to reflections, objects or motion might not be reliably detected or too many objects or motions might be detected. False alarms can be caused by:
  - Reflective backgrounds
  - Glass (glazed building frontages)
  - Water as a background
  - Light beams moving in the dark
- Sudden appearance of spotlights, moving headlights or torch beams lightening up an area can be mistaken for an object.
- Large areas of reflected light can also cause spurious motion detection. However, light reflections caused by falling raindrops, for example, are small enough to be ignored for statistical purposes and owing to the uniform nature of their motion.
- Motion of vegetation due to wind is covered for slow, continuous and uniform wind. If this motion overlaps with objects, false as well as missed detections are possible. To avoid this, adjusting the camera position is necessary.
- Strong wind, storms and heavy blasts from different directions, especially in the foreground of a scene, can trigger false alarms.
Suddenly appearing sharp shadows of clouds, trees and buildings can be mistaken as objects. Soft shadows are covered by the algorithm.

The outline of an object in strong sunlight with a crisp shadow may include the shadow of the object. Consider this for aspect ratio and object size filters. Soft shadows are covered by the algorithm.

A constant background is necessary in order to detect motion reliably and to assign that motion to a particular object. The more the background changes, the harder it is to distinguish moving objects from the background. For example, a person walking in front of a hedge that is moving in the wind will very probably not be detected.

If objects cannot be distinguished from each other or from the background, the motion of an individual object cannot be detected, for example, individuals in a large crowd or a idle object in a large crowd.

Merging effects can occur when objects standing very close together or closely passing each other. Merging effects are visible through a common outline over more objects. This means that a new bigger object appears in the scene and the former detected and tracked object get lost, including all effects on the selected detection tasks. The same effect happens when this object is split in separate objects. To avoid this, check the camera scene, optimize the camera position and configure the software accordingly.

The detection and analysis of objects entering the image will be delayed until significant size and motion have been observed. To avoid this, center all evaluations in the image. With Intelligent Video Analytics on CPP6 and CPP7 cameras, the sensitivity parameter allows you to choose additionally a trade-off between fast object detection and less false alarms due to insignificant motion.

Using the Click-object-in-field function, the quality of the metric results (size, speed, aspect ratio) very much depends on the correct calibration. Observe that the color filter used in this function is related to the outlined area of an object. In most cases this outlines include additional surrounding information like the background, for example, the road asphalt. To obtain the best result for the desired object, we recommended that you delete these unwanted colors in the histogram.

**Minimal object size and processing resolution:**

(Intelligent Video Analytics / Essential Video Analytics)

The Intelligent Video Analytics and Essential Video Analytics algorithm use different processing resolutions on different devices and for different image aspect ratios. Here the processing resolutions for different video aspect ratios.

- Essential Video Analytics
  - 4:3 - 320x240
  - 16:9 - 320x180

- Intelligent Video Analytics (CPP6/7), 3D tracking on, noise suppression OFF / MEDIUM, for moving / started / stopped objects
  - 1:1 - 640x640
  - 4:3 - 640x480
  - 16:9 - 640x360

- Intelligent Video Analytics (CPP6/7), 3D tracking off or noise suppression STRONG or placed/taken objects
  - 1:1 - 320x320
  - 4:3 - 320x240
  - 16:9 - 320x180

- Intelligent Video Analytics (CPP4)
  - 5:4 - 255x204
In corridor mode, the height and width are switched. The Intelligent Video Analytics and Essential Video Analytics algorithm can reliably detect objects that have at least 20 square pixel in this internal resolution, e.g. 3x8 pixel for an upright person.

**Limitations of automatic object type classification:**
(Intelligent Video Analytics / Essential Video Analytics)

**Note:** A camera calibration is required for object classification. The **3D tracking** mode must be selected.

- No differentiation of crawling or rolling persons from animals. Only upright walking or standing persons are classified as persons.
- Persons and bikes seen from the front are easily confused. A bike from the front will only be classified as such if it is fast enough, otherwise it will be classified as a person.
- No differentiation between bicycle and motorbike.
- Small objects with only a few pixel can be confused (for example, objects far away from the camera)
- All objects start as an unknown object. They are only classified over the time if the object class can be determined sufficiently reliable.

**Limitations of color configuration:**
(Intelligent Video Analytics / Essential Video Analytics)

If you are specifically looking for objects in motion with certain color properties, take the following into consideration:

- An object is almost never displayed in a consistent color in the image data. Pixels on the outer edge of a detected object in particular often contain the color information of the background and not the object. Objects such as automobiles comprise a variety of parts (body, windows, tires). Each individual part of the object is displayed in a different color. For example, the mudguards in red and the tires in black.
- The color properties of an object depend upon the lighting conditions. If the lighting conditions in a captured image changes, then the captured color of the object also changes. Objects on a street appear in different hues depending on the time of day and weather conditions.
- An object that changes its position or direction of motion may then appear with different color properties. For example, automobiles are often marked on the side in color but not on the back. When people are seen from the front, the hue of the face determines the color impression; however, if the person turns around, the color properties are then defined by the hair or headdress.

**Limitations of 3D tracking mode:**
(Intelligent Video Analytics / Essential Video Analytics)

**Note:** A calibration of the scene is required. If the scene is not well calibrated, the tracking can deliver wrong or no results.

- All objects must move on a single, flat ground plane. Multiple floors, staircases and vertical object motion can lead to wrong results.
- A camera height of more than 2.5 meters is required. A camera height of more than 3 meters offers the best results.
- Objects that are located entirely above the horizon are not detected, for example, flying objects. In **3D tracking** mode object motion is restricted to the ground plane.
Limitations of 3D people tracking:
(Intelligent Video Analytics / Essential Video Analytics)

**Note:** A camera calibration is required for object classification. The 3D people tracking mode must be selected.

- Top-down views require a camera height of more than 3 meters. A camera height of more than 4 meters offers the best results.
- Select a camera lens so that the head diameter of a person is between 7% and 14% of the screen width and 8% and 16% of the screen heights.
- Other moving objects, reflections on the ground, blinking lights, changing light conditions, shadows, trolleys or persons carrying bags or umbrellas can lead to wrong counting results.
- Children close to other persons cannot be detected.
- If the respective number of people in the scene is exceeded, more and more frames without metadata are created. The tracking will continue as long as possible.

The number of people in a scene that can be tracked in real time is:
- Approximately 10 for Intelligent Video Analytics on CPP4 cameras.
- Approximately 20 for Intelligent Video Analytics on CPP6 and CPP7 cameras.
- Approximately 10 for Essential Video Analytics.
- Line counting at the edge of the field of view may not work.
- 3D people tracking is not possible in low light conditions.
- No differentiation between persons and objects with similar size (for example, suitcases, strollers).
- People with bags could be detected as multiple persons.

Limitation of counting:
(Intelligent Video Analytics / Essential Video Analytics)
- Partly concealed objects and objects that cannot be tracked well, because of speed, background conditions or size, can cause false counting results.

Limitations of panoramic cameras:
(Intelligent Video Analytics / Essential Video Analytics)
- The algorithms are only used on the circle view. The results are transformed into the panorama view.
- Camera calibration is possible, but the calibration wizard is not available.

Limitations of geolocation:
(Intelligent Video Analytics / Essential Video Analytics)
**Note:** A camera calibration is required. To achieve better performance, activate the 3D tracking mode.
- Tracking is only possible on a single ground plane.
- A viewer is needed to show the geolocations on a map.

Limitations of idle/removed object detection:
(Intelligent Video Analytics / Essential Video Analytics)
- **Placed objects / Taken objects** detection is most robust if the object that is placed or taken is much smaller than the object which handles it.
- If a person places or removes a bike, the bike can be detected as placed / taken or as started / stopped as the bike is similar in size to the person. Therefore, check for all idle / removed objects if this is relevant.
- Cars should always be detected as started / stopped objects as they are much larger than persons entering or leaving them.
With Intelligent Video Analytics on CPP6 and CPP7 cameras, in regions with a lot of background motion, only stopped objects are detected. Activation of the detection all other idle / removed object types in these regions is only possible by deactivating the noise suppression.

**Limitations of water vehicle tracking:**
(only available with Intelligent Video Analytics on CPP6 and CPP7 cameras)
- The tracking mode is not suitable for tracking people moving along the beach.
- Applications like a lock where water rushes in white foam into the lock after the lock gates open are not supported.
- High waves can cause false alarms.
- Two boats close together and following each other are detected as one boat.

### 3.1.5 Limitations Intelligent Video Analytics Flow

In certain environments the use of this type of motion detection system may not always be advisable. To obtain useful results, observe the following:
- If the computing power is reduced because of enhanced encoding power, fast speeds can no longer be detected.
- The minimum object size for reliable detection must be at least 8 blocks. Each with a size of 8 x 8 QCIF-pixel.
- Objects that cross the camera view in less than 2 seconds cannot be detected.
- Flow can be detected if the velocity and direction of an object is roughly constant for a configurable short period of time or distance
- Textured objects that stand out from the background are more likely to be detected than those that are similar.
- Objects that move backward and forward or move in a zig zag do not trigger flow detection. An object can only trigger flow detection if it predominantly moves in a straight line. However, if objects are temporarily concealed by a tree, for example, detection is not restricted.
- The sensitive area must cover the direction of the movement that should be detected. Multiple sensitive areas must flow seamlessly into one another. Otherwise, no Flow can be detected in this direction.
- Heavy camera movement can cause false alarms and lead to objects not being detected.
- To detect slow moving objects the range of the main flow must be at least 45°.
- To detect temporarily covered objects set the activity value very high.

### 3.1.6 Licenses

Intelligent Video Analytics and Essential Video Analytics are available on all suitable cameras ex work. No license is needed. Note however, that some previous CPP4 cameras are only prepared for using the Intelligent Video Analytics software. These cameras need licenses.

**Notice!**

Upgrading Intelligent Video Analytics versions
If you have already licensed an earlier version of Intelligent Video Analytics for the device, you simply need to upgrade the firmware of the device. Then the license is automatically upgraded. A new license key is not required. No fee will be charged.
Notice!
You obtain the current firmware from your customer service or from the download area on
our Internet site.
Upgrade the firmware directly by using the Web browser view of the device or by using
Configuration Manager.

3.2 MOTION+
MOTION+ can detect and analyze changes in the signal using image processing algorithms.
Such changes can be due to motion in the camera's field of view.
Thereby MOTION+ detects changes in the image by comparing the current image with a some
seconds older image.
The changes are aggregated in detection blocks. You can configure how many of these
detection blocks must indicate changes over which amount of time before generating an alarm
event.

3.2.1 Use cases
MOTION+ is available on all Bosch IP cameras and suitable for event based recording.

Notice!
For proper intrusion detection, use the Essential Video Analytics or IVA Intelligent Video
Analysis program.

3.2.2 Limitations MOTION+
Observe the following limitations when using MOTION+:
- Due to reflections, objects or motion might not be reliably detected or too many objects
  or motions might be detected. False alarms can be caused by:
  - Reflective backgrounds
  - Glass (glazed building frontages)
  - Water as a background
  - Light beams moving in the dark
- Sudden appearance of spotlights, moving headlights or torch beams lightening up an area
  can be mistaken for an object.
- Large areas of reflected light can also cause spurious motion detection. However, light
  reflections caused by falling raindrops, for example, are small enough to be ignored for
  statistical purposes and owing to the uniform nature of their motion.
- Motion of vegetation due to wind is covered for slow, continuous and uniform wind. If
  this motion overlaps with objects, false as well as missed detections are possible. To
  avoid this, adjusting the camera position is necessary.
- Strong wind, storms and heavy blasts from different directions, especially in the
  foreground of a scene, can trigger false alarms.
- Suddenly appearing sharp shadows of clouds, trees and buildings can be mistaken as
  objects. Soft shadows are covered by the algorithm.
- The outline of an object in strong sunlight with a crisp shadow may include the shadow of
  the object. Consider this for aspect ratio and object size filters. Soft shadows are covered
  by the algorithm.
- A constant background is necessary in order to detect motion reliably and to assign that
  motion to a particular object. The more the background changes, the harder it is to
distinguish moving objects from the background. For example, a person walking in front
of a hedge that is moving in the wind will very probably not be detected.
3.2.3 Licenses
MOTION+ is activated on all suitable cameras ex work. No license is needed.

Notice!
You obtain the current firmware from your customer service or from the download area on our Internet site.
Upgrade the firmware directly by using the Web browser view of the device or by using Configuration Manager.

3.3 Tamper detection
The built-in tamper detection allows you to detect camera manipulations. An alarm event can be triggered as soon as the camera is moved, partially obscured, severely defocused, covered or sprayed.

3.3.1 Use cases
The feature is suitable for the following use cases:
- Detecting camera blinding
- Detecting whether camera is moved off target
- Detecting insufficient overall illumination
- Detecting idle or removed objects

3.3.2 Limitations Tamper detection
The Tamper detection feature is not available on thermal cameras.

3.3.3 Licenses
No license is needed. You must activate the Tamper detection feature in the VCA configuration.

Notice!
You obtain the current firmware from your customer service or from the download area on our Internet site.
Upgrade the firmware directly by using the Web browser view of the device or by using Configuration Manager.
4 Basics for Intelligent and Essential Video Analytics

This chapter describes basic information when using Intelligent Video Analytics and Essential Video Analytics.

4.1 Camera image

A camera image is that part of an area which is monitored by the camera.

4.2 Objects

Objects are typically people or vehicles moving within the area seen by the camera. Objects can be filtered according to certain properties (size, aspect ratio, direction of movement, speed, location, color). An alarm event can be generated if objects match certain parameters. Objects that do not match the criteria you define are filtered out and do not generate an alarm event.

In general the base point of an object is relevant for generating an alarm event. Some tasks allow you to make another selection.

4.3 Object triggers

Object triggers allow you to select the exact moment, when an object generates an alarm event. The basis for analysis is either the virtual frame (bounding box) around an object or the calculated 3D base point for 3D tracking and 3D people tracking.

The default behaviour for alarming is: Object base point.

Notice!

To display the virtual frame around an object: Right-click into the camera image, then click Show > Object Bounding Boxes.

To display the trajectory of an object: Right-click into the camera image, then click Show > Trajectories

The following object triggers are available:

- **Object base point**: An object generates an alarm if the base point of the object is inside the sensitive area.

- **Object center**: An object generates an alarm if the center of the object is inside the sensitive area.

- **Edge of box**: An object generates an alarm if one of the edges of the virtual frame around the object is inside the sensitive area.
Complete box: An object generates an alarm if the virtual frame around the object is completely inside the sensitive area.

Notice!
When configuring the Leaving field task, note that the alarm is generated as soon as the object is no longer in the field. Thus the different object triggers behave as follows:
The object trigger Edge of box generates an alarm event if no edge of the object is any longer within the field and thus the object is completely outside the field.
The object trigger Complete box generates an alarm event as soon as any part of the virtual frame around the object is outside the field.

The object triggers are available in all tasks that enable you to restrict the detection area to a field.

- Configuring the Entering field task, page 59
- Configuring the Leasing field task, page 60
- Configuring the Counter task, page 63

4.4 Calibration
Camera calibration is necessary to detect objects correctly for the following features:
- Object filter for size and speed in the metric or imperial system.
- Object filter of the following type:
  - Upright persons
  - Bikes
  - Cars
  - Trucks
- 3D tracking mode, which tracks objects on the ground plane
- 3D people tracking mode, which interprets everything as person and tracks these on the ground plane. Use this tracking mode for people counting, optimally for a top-down view.
- Geolocation, the output of the positions of tracked objects in relation to the camera position.
- Double detection distance (only for Intelligent Video Analytics on CPP6 and CPP7 cameras).
With camera calibration a link is made for each camera position between the size of the real-life situation and the dimensions as they appear on the camera image. For example, you tell the software that an object on the camera image is 2 m high in reality. To obtain a calibration, some known camera values are set automatically by the system. Other values must be entered manually, for example, tilt angle, roll angle, camera height, focal length (if variable).

**Notice!**
For AUTODOME, MIC and CPP7 cameras the roll and tilt angle is set automatically. For AUTODOME, MIC and FLEXIDOME cameras, the focal length is set automatically. All these values can also be changed manually on demand. To update changes in camera position and orientation, close the VCA configuration and open it again.

| Tilt angle [°] | The angle between the horizontal and the camera. A tilt angle of 0° means that the camera is mounted parallel to the ground. A tilt angle of 90° means that the camera is mounted vertically in birds eye view perspective. The flatter the tilt angle is set, the less accurate the estimate of object sizes and speeds will be. The settings must be between 0° and 90°. Estimates are no longer possible when you have reached 0°. |
| Roll angle [°] | The angle between the roll axis and the horizontal plane. The setting can deviate from the horizontal by up to 45 degrees. |
| Elevation [m] | The vertical distance from the camera to the ground plane of the captured image. Typically the elevation of the mounted camera above the ground. |
| Focal length [mm] | The focal length is determined by the lens. The shorter the focal length, the wider the field of view. The longer the focal length, the narrower the field of view and the higher the magnification. |

**Notice!**
The camera must be recalibrated each time the camera position is changed.

**See also**
- Calibrating the camera, page 68
- Configuring the global settings, page 70
4.5 **Object classification**

Object classification is used to simplify the usage of the Intelligent Video Analytics program by providing an automatic object type detection based on specific values typically for this objects types.

In some scenarios, the differentiation of objects is needed, for example, a gate where only cars are allowed to pass but no persons.

The object classification differentiates between:

- **Upright persons**
- **Cars**
- **Trucks**
- **Bikes** (either bicycle or motorbike)

**Notice!**

To activate object classification, calibrate the camera and choose a 3D tracking mode.

To display the object classification flags, right-click into the camera image, then click **Show > Class Flag**.

- Configuring the Idle object task, page 57
- Configuring the Entering field task, page 59
- Configuring the Leaving field task, page 60
- Configuring the tracking parameters, page 71

4.6 **Field**

Fields are polygons that cover a certain area, for example an entrance or the open space in front of a barrier. These fields are created by you. Objects that move within a field can generate an alarm event.

See also

- Configuring the Object in field task, page 45
- Configuring the Leving field task, page 60
- Configuring the Entering field task, page 59

4.6.1 **Displaying fields in the camera image**

Fields are displayed as follows:

A field that is not being used in any tasks is displayed in gray.
A field that is being used in a task is displayed in green. Used fields can be edited but not deleted.

A field for which there is currently an alarm event is displayed in red.

**4.6.2 Creating and editing a field**

You can create a new field. A field can also be edited at any time. This includes:

- Changing the field size
- Moving the field
- Inserting or deleting nodes

To create a new field:

1. Click into the camera image to begin with the first corner of the field, then click again for each corner. Finish the field by double-clicking.

To change the size of the field:

1. Select the field.
2. Drag the line or the corners (nodes) of a field to the desired position in the camera image.

To move a field:

1. Select the field.
2. Drag the field as a whole to the desired position in the camera image.

To insert a corner (node):

1. Select the field.
2. Right-click a line, then click **Insert Node**.
   or
   Double-click a line. A node is automatically inserted.

To delete a corner (node):

1. Select the field.
2. Right-click a node, then click **Delete Node**.

**4.7 Line**

A line can be compared to a virtual trip wire. Objects that cross a line you have defined in a pre-defined direction can trigger an alarm event.

**See also**

- Configuring the Crossing line task, page 47
4.7.1 Displaying lines in the camera image

Lines are displayed as follows:

A line that is being used in a task is displayed in green. Used lines can be edited but not deleted.
The triangle marks the direction in which an object must cross a line in order to generate an alarm event. If an alarm event is generated each time the line is crossed, regardless of the direction, no arrow is displayed.
A line can consist of several segments.

A line that is not being used in any tasks appears dimmed.

Notice!
If a line is integrated into a task, you can choose the direction in which the line must be crossed in order to trigger an alarm.

4.7.2 Creating and editing a line

You can create a new line. A line can be edited at any time. This includes:

– Inserting and deleting nodes
– Moving nodes (changing size and direction)
– Moving lines

To create a new line:

1. Click into the camera image. Each click creates a new node of the line. Double-click to finish the line.

To insert a node:

1. Select the line.
2. Right-click a line or a segment of the line, then click Insert Node.
   or
   Double-click a line. A node is automatically inserted.

To delete a node:

1. Select the line.
2. Right-click a node, then click Delete Node.

To change the size and direction of a line:

1. Select the line.
2. Drag a node and move it to the desired position.

To move the line:

1. Drag the line and move it to the desired position.

4.8 Route

Objects that move along a route you have defined in a pre-defined direction can trigger an alarm event. It is possible to include deviations from this route using the relevant tolerance defaults.

Notice!
If a route is integrated into a task, you can select the direction in which movement along the route must trigger an alarm.
See also
– Configuring the Following route task, page 52

4.8.1 Displaying routes in the camera image

Routes are displayed as follows:

A route that is not being used in any tasks is displayed in gray.

A route that is being used in a task is displayed in green. Used routes can be edited but not deleted.

A triangle marks the direction in which an object must follow the path in order to generate an alarm event. If an alarm event is generated each time there is movement along the route, regardless of the direction, no arrow is displayed.

4.8.2 Creating and editing a route

You can create a new route. A route can be edited at any time. This includes:
– Inserting or deleting nodes
– Moving nodes (changing the course of a line)
– Changing the tolerance range
– Moving routes

A route is displayed as a line with an assigned direction. The line includes a tolerance range, which is displayed as an area. The tolerance range is axis-symmetric to the respective section of the central line. An extension to the tolerance range can be individually defined at any node.

To create a new route:

1. Click into the camera image. Each click creates a new node of the route. Double-click to finish the route.

To insert a node:
1. Select the route.
2. Right-click a line, then click Insert Node.
   or
   Double-click a line. A node is automatically inserted.

To delete a node:
1. Select the route.
2. Right-click a node, then click Delete Node.

To change the course of the route:
1. Select the route.
2. Drag a node of the route and move it to the desired position.

To change the tolerance range:
1. Select the route.
2. Drag the marking next to a node and move it to the desired position.

To move the route:
1. Drag the route and move it to the desired position.

4.9 Tasks

The result of a task is usually an alarm event. An alarm event can be analyzed in a CCTV system in many ways. In this way, a recording can be started, a door closed or an e-mail sent, for example.
Examples of typical events that can trigger an alarm:
- An object moves within a defined area.
- An object crosses one or more lines, for example an automobile drives into a parking space.
- An object stops in certain areas without any target-specific motion (loitering).
- An object moves along a defined route.
- A piece of luggage is set down (idle object).
- An object is removed (theft).
- The camera is tampered with.

Notice!
You can configure the Counter and Occupancy tasks not to generate an alarm event but deliver the counts only.

See also
- Configuring tasks, page 45

4.9.1 Creating and editing a task
To create a new task:
- Click New, select the task, then click OK.
To change the task name:
- Click the task, then click the name of the task and change it.
  Note: A task has an red background if an alarm event is currently being triggered by this task.
To edit a task:
- Select the task, click Edit, then change the settings.
  or
- Double click the icon to the left of the task name to open the task for editing.
To activate a task:
- In the Alarm column, click the check box to the right of the task name.
To rename a task:
- Select the task, then click the task name and enter the new name.
To delete a task:
- Select the task, then click Delete.

4.10 Conditions in tasks
You can precisely limit the property (condition) of an object that triggers an alarm event. Objects that do not correspond to the properties specified do not trigger an alarm event. A property is used to search for an object if you activate the relevant option. After an option has been activated, the property range can be set directly or with the manipulable visualization provided. Properties can also be adopted from a tracked object by selecting it. This selected object is then marked with a yellow flag.

Object Area [m²]
Only objects whose size (the area covered) corresponds to the entered values generate an alarm event.

Aspect Ratio V/H
Objects whose aspect ratio corresponds to the entered values generate an alarm event.
The minimum and maximum ratios are graphically displayed in the camera image as two yellow rectangles. By default, values are set with which all objects trigger an alarm event.

The ratio is the quotient of the vertical and horizontal extension of the object in the image captured by the camera. The actual aspect ratio can deviate from this.

The aspect ratio of a vehicle changes if it changes its direction by 90°.

Persons captured directly from above always have the same aspect ratio in the image, irrespective of their actual size.

**Note:** The aspect ratio of a person changes if the person falls down or stands up, except the **3D people tracking** mode is selected. In **3D people tracking** mode the person shape remains in upright position.

**Speed [km/h]**

Only objects moving at a speed that corresponds to the entered values generate an alarm event.

---

**Notice!**

The speed of a motion at a right angle to the camera can be determined much more accurately than the speed of a motion directly toward or away from the camera.

The speed of closer objects can be determined much more accurately than that of objects further away.

---

**Object moves at a right angle to the camera:**

speed is detected more accurately

**Object moves in camera's line of sight:**

speed is detected less accurately

---

**Direction 1 [°] / Direction 2 [°]**

Only objects moving in a certain direction generate an alarm event. The direction is determined by entering an angle.

0° corresponds to the direction of motion from right to left.

It is counted counter-clockwise.
Another direction can be optionally entered. In this way, movements are captured in two directions. The direction is graphically displayed by a yellow circle segment in the camera image.

**Notice!**
Only use the speed and direction filters for detecting truly significant movements; select your settings to ensure the most robust results possible.

### 4.11 Color

You can describe the color properties of the searched object. The color properties of an object are mainly used in forensic searches to detect moving objects by their color. As objects rarely appear in one single color, the colors are detected by analyzing the different proportions of color according to their frequency. This means that, for example, you can search for objects that consist of up to 25% dark red pixels but also include up to 20% light gray pixels at the same time.

Color properties used for filtering can be adopted and refined using a marked object.

**Notice!**
The detection of color is not possible for objects that are only displayed with very few pixels.

Colors are described using the HSV color model.

1. Color cylinder
   - All colors are displayed in 3D. In the illustration, you see a color cylinder from above, in which the saturation fades from the exterior to the interior and the value fades from the top to the bottom.
   - In the color wheel, the tones used in the search for objects are displayed unshaded.

2. Slider (brightness)
   - Use this slider to select the degree of brightness for the colors. The display shows a higher or lower section of the color cylinder according to the slide control setting.
3 Colors
Colors you can select for the search. The colors are displayed in the squares below the color cylinder.

4 Precision slider.
Defines how exactly the colors must correspond for an object to be detected.
Slider at the far left position: The selected color is not detected.
Slider at the far right position: The selected color must match exactly to be detected.
Note: The accuracy range you have defined with the slider can be used for only one color or can be shared between several selected colors.
This means:
- One color uses the entire accuracy range and the other colors must match exactly.
- All of the colors share less accuracy between each other.

5 Displays the colors you have selected in the color cylinder. The further left the selected color is arranged in the squares, the higher its proportion of the object’s color properties.
The importance of the colors in the search is from left to right: 25%; 20%; 15%; 10%; 5%.
Note: If a lot of different colors with low precision are selected, almost all colors trigger unwanted alarms. We recommend being more selective and precise.

6 Clear
Deletes a selected color.

4.12 Global settings
Intelligent Video Analytics allows frontal face detection. Face information are included in the metadata stream.
Snapshots of the best face images are generated automatically and uploaded to FTP or Dropbox accounts.
You can search for faces using the web page.

Notice!
The Global Settings page informs you whether the selected camera is calibrated. And in case of panoramic cameras, where you must calibrate the camera.

4.13 Sensitive area
Use VCA masks to exclude disturbing objects or areas that are irrelevant for alarm event generation.
Only objects moving outside VCA masks, in the sensitive area of the camera image, are detected as such and generate an alarm event. Objects moving inside VCA masks cannot generate an alarm event even if they are caught by the camera.
In the default setting, the whole camera image is defined as sensitive area.

Notice!
Initial object detection is only performed in sensitive areas. However, the object shape may grow considerably into insensitive areas to include those parts of the object as well.

Examples where we recommend the use of VCA masks:
– Railroad: 
  Passing trains can trigger unwanted motion alarms.
– Public streets: 
  Passers moving across a public space should not be detected in order to save 
  unnecessary computing power and prevent unwanted false alarms.
– Neighboring properties: 
  Areas in which moving objects are not anticipated.
– Sky: 
  Birds or planes can trigger false alarms.
– Trees, bushes or flags that move in the wind.

**Notice!**
Using Intelligent Video Analytics for forensic search in recordings, motion analysis is only possible in the area that was previously marked as the sensitive area in the recording.

**See also**
– *Configuring the sensitive area, page 71*

### 4.14 Loitering

This task generates an alarm event if an object only moves slightly within a certain area for a specified period. The area is defined by a field in the camera image. The alarm can also be restricted to objects within a detection field. This detection field is independent from the evaluated loitering radius. The loitering radius is always centered on the evaluated object. If the object is in motion, the loitering radius moves as well and the loitering condition is re-evaluated based on the former path of the object.

| Examples: | No alarm: 
Object trajectory is in the loitering radius but object is not in the field |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image1.png" alt="Example 1" /></td>
<td><img src="image2.png" alt="Example 2" /></td>
</tr>
</tbody>
</table>
|  | Alarm: 
Object is in the field and the object trajectory is in the loitering radius. 
Loitering radius and detection field are independent. An alarm is also generated if the object but not the complete loitering radius is in the detection field. |
| ![Example 3](image3.png) | ![Example 4](image4.png) |
|  | Alarm: 
Object is in the field and the object trajectory is in the loitering radius. |
| ![Example 5](image5.png) | ![Example 6](image6.png) |
4.15 Crowd fields

A crowd field is that part of the image captured by the camera that is analyzed for crowd detection. Objects moving outside a crowd field cannot generate an alarm event even if they are caught by the camera. Only objects within the crowd field are detected as such. An alarm event is generated if within a crowd field a certain density of objects is reached.

See also
– Configuring the crowd fields, page 73

4.16 Metadata inspection - statistics

Displays histograms with statistics on the relevant detected motions, either for a selected field or for the whole screen. The statistics help you to monitor the properties of a marked object over a longer period of time and to observe the changes. This allows you to refine the filter criteria for objects. For example, you may see accumulations of objects that have not triggered an alarm under the current filter criteria even though this might have been desirable. The creation of the displayed statistics starts as soon as you open the window. The longer the window is left open, the more values will be entered into the statistics.

The statistics show the following histograms:
– Object Area [m²]: accumulation of objects with a certain area.
– Aspect Ratio V/H: accumulation of objects with a certain aspect ratio.
– Speed [km/h]: accumulation of objects moving at a certain speed.
– Direction [°]: accumulation of objects moving in a certain direction.
– Color: Displaying color properties.

See also
– Metadata inspection - statistics, page 74

4.17 Image information

Depending on the configuration of Intelligent Video Analytics and Essential Video Analytics, additional overlays in the image, for example object outlines, can provide more information. These object outlines are displayed in real time and are always synchronized exactly with the moving object. During life view, the metadata arrive one frame after the respective camera image, and thus the outlines do not always exactly surround the object.

<table>

5 Basics for Intelligent Video Analytics Flow

This chapter describes basic information when using Intelligent Video Analytics Flow.

5.1 Tasks

A task describes events that trigger an alarm event when detected in the camera image.

A task can be created using a wizard. Expert users can adapt tasks created in this way to their requirements using Intelligent Video Analytics Task Editor.

Examples of typical events that can trigger an alarm event:
- An overall motion (flow) within an area.
- Motion against the flow.
- The camera is tampered with.
- Crowd or queue detection.

The result of a task is usually an alarm event. An alarm event can be analyzed in a CCTV system in many ways. In this way, a recording can be started, a door closed or an e-mail sent, for example.

See also
- Configuring tasks, page 76

5.1.1 Creating and editing a task

To create a new task:
- Click New, select the task, then click OK.

To change the task name:
- Click the task, then click the name of the task and change it.

Note: A task has an red background if an alarm event is currently being triggered by this task.

To edit a task:
- Select the task, click Edit, then change the settings.
- or
- Double click the icon to the left of the task name to open the task for editing.

To activate a task:
- In the Alarm column, click the check box to the right of the task name.

To rename a task:
- Select the task, then click the task name and enter the new name.

To delete a task:
- Select the task, then click Delete.

5.2 Fields

Fields are polygons that cover a certain area, for example an entrance or the open space in front of a barrier. These fields are created by you. Objects that move within a field can generate an alarm event.

See also
- Configuring the Flow in field task, page 77
- Configuring the Counterflow in field task, page 78
5.2.1 Displaying fields in the camera image

Fields are displayed as follows:

- A field that is not being used in any tasks is displayed in gray.
- A field that is being used in a task is displayed in green. Used fields can be edited but not deleted.
- A field for which there is currently an alarm event is displayed in red.

5.2.2 Creating and editing a field

You can create a new field. A field can also be edited at any time. This includes:
- Changing the field size
- Moving the field
- Inserting or deleting nodes

To create a new field:
1. Click into the camera image to begin with the first corner of the field, then click again for each corner. Finish the field by double-clicking.

To change the size of the field:
1. Select the field.
2. Drag the line or the corners (nodes) of a field to the desired position in the camera image.

To move a field:
1. Select the field.
2. Drag the field as a whole to the desired position in the camera image.

To insert a corner (node):
1. Select the field.
2. Right-click a line, then click **Insert Node**.
   or
   Double-click a line. A node is automatically inserted.

To delete a corner (node):
1. Select the field.
2. Right-click a node, then click **Delete Node**.

5.3 Sensitive area

In the default setting, the whole camera image is defined as sensitive area. Use VCA masks to exclude disturbing objects or areas that are irrelevant for alarm event generation. Only flows outside VCA masks, in the sensitive area of the camera image, are detected as such and generate an alarm event. Flows inside VCA masks cannot generate an alarm event even if they are caught by the camera.
See also
- Configuring the sensitive area, page 79

5.4 Metadata inspection - statistics
Displays histograms with statistics on the relevant detected motions, either for a selected field or for the whole screen.
The statistics help you to monitor the properties of a marked object over a longer period of time and to observe the changes. This allows you to refine the filter criteria for objects. For example, you may see accumulations of objects that have not triggered an alarm under the current filter criteria even though this might have been desirable.
The creation of the displayed statistics starts as soon as you open the window. The longer the window is left open, the more values will be entered into the statistics.
The statistics show the following histograms:
- Slow Speed Direction Histogram [°]
- Medium Speed Direction Histogram [°]
- Fast Speed Direction Histogram [°]
- Activity Histogram [% of area]: accumulation of activity

See also
- Metadata inspection – statistics, page 80

5.5 Image information

Notice!
The Intelligent Video Analytics Flow functionality differs from the Intelligent Video Analytics object recognition. The Intelligent Video Analytics Flow functionality detects an optical flow formed by the movement of individual blocks. Intelligent Video Analytics Flow does not use a camera calibration.

Depending on the configuration of Intelligent Video Analytics Flow, additional overlays in the image can provide further information.

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Red arrows indicate a detected flow that will generate an alarm event in accordance with the current settings.</td>
</tr>
<tr>
<td>Yellow arrows indicate a detected flow that will not generate an alarm event.</td>
</tr>
<tr>
<td>The arrows indicate the direction of movement of the detected block. The length of an arrow indicates the speed of the block. This ensures that movements that have been defined in more detail can be filtered out and will not trigger an alarm.</td>
</tr>
</tbody>
</table>
6 Basics for MOTION+

This chapter describes basic information when using MOTION+.

6.1 Camera image

A camera image is that part of an area which is monitored by the camera.

6.2 Field

Fields are polygons that cover a certain area, for example an entrance or the open space in front of a barrier. These fields are created by you. Objects that move within a field can generate an alarm event.

See also
- Configuring the Detect any motion task, page 82
- Configuring the Motion in field task, page 82

6.2.1 Displaying fields in the camera image

Fields are displayed as follows:

- A field that is not being used in any tasks is displayed in gray.

- A field that is being used in a task is displayed in green. Used fields can be edited but not deleted.

- A field for which there is currently an alarm event is displayed in red.

6.2.2 Creating and editing a field

You can create a new field. A field can also be edited at any time. This includes:
- Changing the field size
- Moving the field
- Inserting or deleting nodes

To create a new field:
- Click into the camera image to begin with the first corner of the field, then click again for each corner. Finish the field by double-clicking.

To change the size of the field:
1. Select the field.
2. Drag the line or the corners (nodes) of a field to the desired position in the camera image.

To move a field:
1. Select the field.
2. Drag the field as a whole to the desired position in the camera image.

To insert a corner (node):
1. Select the field.
2. Right-click a line, then click **Insert Node**.
   
   or
   
   Double-click a line. A node is automatically inserted.

To delete a corner (node):
1. Select the field.
2. Right-click a node, then click **Delete Node**.

### 6.3 Tasks

A task describes events that trigger an alarm event when detected in the camera image (an object moving within a defined area, for example).

The result of a task is usually an alarm event. An alarm event can be analyzed in a CCTV system in many ways. In this way, a recording can be started, a door closed or an e-mail sent, for example.

**See also**
- *Configuring tasks - general, page 82*

#### 6.3.1 Creating and editing a task

To create a new task:
- Click **New**, select the task, then click **OK**.

To change the task name:
- Click the task, then click the name of the task and change it.

  **Note:** A task has a red background if an alarm event is currently being triggered by this task.

To edit a task:
- Select the task, click **Edit**, then change the settings.
  
  or
  
  Double click the icon to the left of the task name to open the task for editing.

To activate a task:
- In the **Alarm** column, click the check box to the right of the task name.

To delete a task:
- Select the task, then click **Delete**.

### 6.4 Sensitive Area

Sensitive area is that part of the camera image where motion can be detected.

Use VCA masks to exclude disturbing objects or areas that are irrelevant for alarm event generation.

Only objects moving outside VCA masks, in the sensitive area of the camera image, are detected as such and generate an alarm event. Objects moving inside VCA masks cannot generate an alarm event even if they are caught by the camera.

In the default setting, the whole camera image is defined as sensitive area.

Examples where we recommend the use of VCA masks:

- Railroad:
  - Passing trains can trigger unwanted motion alarms.

- Public streets:
  - Passers moving across a public space should not be detected in order to save unnecessary computing power and prevent unwanted false alarms.

- Neighboring properties:
  - Areas in which moving objects are not anticipated.

- Sky:
Birds or planes can trigger false alarms.
- Trees, bushes or flags that move in the wind.

**Notice!**
Using MOTION+ for forensic search in recordings, motion analysis is only possible in the area that was previously marked as the sensitive area in the recording.

**See also**
- Configuring the sensitive area, page 83

## 6.5 Metadata inspection – statistics

When you select the **Metadata Inspection** tab, some histograms with statistics on the relevant detected motions are displayed, either for a selected field or for the whole screen. The statistics help you to monitor the properties over a longer period of time and to observe the changes. This allows you to refine the filter criteria. The creation of the displayed statistics starts as soon as you open the MOTION+ window. The longer the window is left open, the more values will be entered into the statistics. The statistics show the following histograms:
- **Cell Cluster Histogram [% of Whole Screen]**
- **Activity Histogram [% of area]**

**See also**
- Metadata inspection, page 84
- Configuring the Motion in field task, page 82
7 Basics for Tamper detection

This chapter describes basic information when using the Tamper detection.

Reference image
A fixed video image that shows the desired state concerning camera orientation and scene illumination, for example.

Reference check
Continuously compares the reference image with the current video image. If the current video image in the marked areas differs from the reference image, an alarm is triggered. This detects tampering that would otherwise not be detected.

The feature is suitable for the following use cases:
– Detecting camera blinding
– Detecting whether camera is moved off target
– Detecting insufficient overall illumination
– Detecting idle or removed objects

See also
– Configuring Tamper detection, page 85
8 Starting VCA applications

You can start video analysis (VCA) as follows:
– Use the Configuration Manager program.
  or
– Use the Web browser view of the device.

The following applications are available:
– Intelligent Video Analytics
– Intelligent Video Analytics Flow
– Essential Video Analytics
– MOTION+
– Tamper detection

Notice!
You must move the camera to the required position first in each case. When using AUTODOME and MIC cameras, the individual presets must be specified before configuring the VCA application for each preset. All of the settings you make, relate to the selected camera position. This means that you must reconfigure the VCA application for this camera whenever you change the direction or position of the camera.

See also
– Starting VCA using Configuration Manager, page 42
– Starting VCA using Web browser, page 43

8.1 Starting VCA using Configuration Manager

The Configuration Manager program can be installed on any Windows PC that communicates with the respective device over a network. The Configuration Manager program needs no license and no additional programs are required to analyse live images.

The system requirements and operation of Configuration Manager are described in the Configuration Manager manual.

To start VCA using Configuration Manager:
1. Start Configuration Manager.
2. In the toolbar, click the My Devices tab, then select the device for which you wish to configure VCA.
   In the View area, click the VCA tab.
   The VCA start page is displayed and the camera image appears to the right.
3. In the Operating mode list, select Profile #1 or Profile #2.
   Note: To rename the profile, click.
   There are 16 profiles available for AUTODOME cameras. Each profile can be used for one preset.
4. Only AUTODOME cameras: In the Scene list, select an entry.
   The camera positions for individual presets must be defined in advance. These presets may already be named individually.
   Only presets that are not yet linked to one of the profiles are available.
5. If necessary, select an Aggregation time [s] between 0 and 20 seconds.
   The aggregation time always starts when an alarm event occurs. It extends the alarm event by the value set. This prevents alarm events that occur in quick succession from triggering several alarms and successive events in a rapid sequence. No further alarm is triggered during the aggregation time. The post-alarm time set for alarm recordings only starts once the aggregation time has expired.
6. In the **Analysis type** list, select the respective VCA type.
   If you change the analysis type, the motion detection and tamper detection parameters revert to the default settings.
   As soon as the analysis becomes active, meta data is generated and, depending on the configuration, additional information is overlaid on top of the camera image — an object bounding box for example.

7. Configure the VCA type using the following tabs.
   - **Tasks**
   - **Metadata Generation**
   - **Metadata Inspection**
   - **Tamper Detection**

**Notice!**
In the VCA configuration you can stop the video image by clicking the **Freeze** button.

**Notice!**
If the VCA configuration of this camera is in use, no other users can configure VCA of this camera at the same time. Only the first user is able to do this. Other users receive a message that configuration is not possible.

### 8.2 Starting VCA using Web browser

You can also start the VCA application using the Web browser view of the device.

To start VCA using the Web browser view:

1. Open the Web browser view of the device. To do this, in the address bar of the Web browser enter `http://<IP address of the device>`.
2. Click **Configuration > Alarm > VCA**.
   The VCA start page is displayed and the camera image appears to the right.
3. In the **VCA configuration** list, select **Profile #1** or **Profile #2**.
   **Note:** If necessary, click 📝 to rename the profile.
   There are 16 profiles available for AUTODOME cameras. Each profile can be used for one preset.
4. Only AUTODOME cameras: In the **Scene** list, select an entry.
   The camera positions for individual presets must be defined in advance. These presets may already be named individually.
   Only presets that are not yet linked to one of the profiles are available.
5. If necessary, select an **Aggregation time [s]** between 0 and 20 seconds.
   The aggregation time always starts when an alarm event occurs. It extends the alarm event by the value set. This prevents alarm events that occur in quick succession from triggering several alarms and successive events in a rapid sequence. No further alarm is triggered during the aggregation time. The post-alarm time set for alarm recordings only starts once the aggregation time has expired.
6. In the **Analysis type** list, select the respective VCA type.
   If you change the analysis type, the motion detection and tamper detection parameters revert to the default settings.
   As soon as the analysis becomes active, meta data is generated and, depending on the configuration, additional information is overlaid on top of the camera image — an object bounding box for example.

7. If required, in the **Tamper detection** pane, enter your settings for tamper detection.
8. Click **Configuration**.  
Configure the VCA type using this window.

**Notice!**  
In the VCA configuration you can stop the video image by clicking the **Freeze** button.

**Notice!**  
If the VCA configuration of this camera is in use, no other users can configure VCA of this camera at the same time. Only the first user is able to do this. Other users receive a message that configuration is not possible.
9 Configuring Intelligent and Essential Video Analytics

This chapter describes the configuration and settings for Intelligent Video Analytics and Essential Video Analytics.

9.1 Configuring tasks

- in Configuration Manager: **VCA** tab > **Profile #1** or **Profile #2** and Intelligent Video Analytics or Essential Video Analytics > **Tasks** tab
- in Web browser: **Alarm** > **VCA** > **Profile #1** or **Profile #2** and Intelligent Video Analytics or Essential Video Analytics > **Configuration** button > **Tasks** tab

A task is always created or edited using a wizard. When you use the wizard to create or edit a task, you have access to the camera image and the commands, for example to create, edit or delete fields. Expert users can adapt tasks to their requirements using VCA Task Script Editor. You can immediately recognize from the color of object outlines whether an object will trigger an alarm with the given settings.

See also
- **Tasks**, page 35

9.1.1 Configuring the Detect any object task

- in Configuration Manager: **VCA** tab > **Profile #1** or **Profile #2** and Intelligent Video Analytics or Essential Video Analytics > **Tasks** tab
- in Web browser: **Alarm** > **VCA** > **Profile #1** or **Profile #2** and Intelligent Video Analytics or Essential Video Analytics > **Configuration** button > **Tasks** tab

When you work with Intelligent Video Analytics and Essential Video Analytics for the first time, the default task **Detect any object** is already available. This task detects all objects in the entire camera image. Initially, even the global settings are preset in such a way that no object is excluded.

This first preset task corresponds in the configuration to the task type **Object in field**.

9.1.2 Configuring the Object in field task

- in Configuration Manager: **VCA** tab > **Profile #1** or **Profile #2** and Intelligent Video Analytics or Essential Video Analytics > **Tasks** tab
- in Web browser: **Alarm** > **VCA** > **Profile #1** or **Profile #2** and Intelligent Video Analytics or Essential Video Analytics > **Configuration** button > **Tasks** tab

This task generates an alarm event if an object moves within a certain area. The area is defined by a field in the camera image.

**Note:** This task can be used for Intelligent Tracking.

To select the task:
1. On the **Surveillance Tasks** page, click **New**.
2. On the **Create a Task** page, select **Object in field**, then click **OK**.

**Define the Field page**

1. Select a field from the list or create a new one.

   To create a new field, click into the camera image to start with the first corner of the field, then click again for each corner. Finish the field by double-clicking.

   **Note:** You can also select **Whole screen** or edit an existing field.
2. In the **Debounce time [s]** box, enter the minimum time that an object must remain within the field before it triggers an alarm. To do this, select the field in the camera image first, then enter the value. If necessary, enter the time for each field.

   **Note:** By entering a value, you can prevent the triggering of multiple alarm events by objects that are constantly moving toward and away from the boundary of the field.

3. In the **Intersection trigger** list, select the object trigger.
   - **Object center**: An object generates an alarm if the center of the object is inside the sensitive area.
   - **Edge of box**: An object generates an alarm if one of the edges of the virtual frame around the object is inside the sensitive area.
   - **Complete box**: An object generates an alarm if the virtual frame around the object is completely inside the sensitive area.
   - **Object base point**: An object generates an alarm if the base point of the object is inside the sensitive area.

**Filter by Object Class page**
Limit the object classes that trigger an alarm.
   - Select the desired check boxes (**Upright persons**, **Bikes**, **Cars**, **Trucks**).

**Approximation page**
Define approximations for the different object properties. You can adopt these values as the basis for the settings in the next step.

1. Click a moving object in the camera image. The values for object size, aspect ratio, speed and direction are displayed for the marked object. The colors of the object are also displayed.

   **Note:** The properties of an object are always changing. You adopt the properties of the object at the time of clicking.

2. Click the **Apply values** check box if you want to use the properties of the marked object.

3. Move the **Precision** slider of each property to define how exactly they must correspond for an object to be detected.

   The further to the right the slider is set, the more accurate the description of the property of the searched object that is to trigger an alarm. Slider set to the left, property is ignored and the value is not adopted in the next step.

**Filter by Object Conditions page**
Limit the properties of an object that triggers an alarm event. Objects that do not correspond to the properties specified here do not trigger an alarm event.

1. In the **Object Area [m²]** box, enter a minimum and a maximum value for the size.

2. In the **Aspect Ratio V/H** box, enter a minimum and a maximum value or select a rectangle in the camera image and change the size by dragging a node.

3. In the **Speed [km/h]** box, enter a minimum and a maximum value for the speed.

4. In the **Direction 1 [°] / Direction 2 [°]** boxes, enter a minimum and a maximum value (angle) to define the directions of a moving object. Only flows moving in these directions will trigger an alarm event.

   The directions are displayed as yellow circle segments in the camera image.

   You can also define the direction as follows:
   - Place the pointer in the yellow circle segment, press and hold the mouse button, then turn the segment.
   - Place the pointer over one of the edges of the yellow circle segment, press and hold the mouse button, then move the edge.
**Filter by Object Colors page**

Describe the color property of the searched object.

1. Move the slider to select the degree of brightness for the colors.
2. Select up to five 5 colors for the search. To do this, select a square, then click the desired color segment.
3. Move the *Precision* slider to determine how accurately the colors must match the object colors.
4. If necessary delete a selected color. To do this, select a square, then click *Clear*. If there are colors to the right of the deleted position, then they will move up automatically and receive a higher proportion of the object's color properties.

**See also**
- *Object triggers*, page 21

- *Field*, page 24
- *Conditions in tasks*, page 28
- *Color*, page 30

### 9.1.3 Configuring the Crossing line task

**In Configuration Manager:** *VCA* tab > Profile #1 or Profile #2 and *Intelligent Video Analytics* or *Essential Video Analytics* > *Tasks* tab

**In Web browser:** *Alarm* > *VCA* > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > Configuration button > *Tasks* tab

This task generates an alarm event if an object crosses one or more virtual lines.

**Note:** This task can be used for Intelligent Tracking.

To select the task:

1. On the *Surveillance Tasks* page, click *New*.
2. On the *Create a Task* page, select *Crossing line*, then click *OK*.

**Define the Lines page**

1. From the list, select one of the lines that have already been created or click a line in the camera image.
   - **Note:** You can also create a new line or edit an existing one.
2. Select a second and a third line, if necessary.
3. In the *Debounce time [s]* box, enter the minimum time that an object must be observed first before crossing the line and then also after crossing the line to trigger an alarm. To do this, select the line in the camera image first, then enter the value. If necessary, enter the time for each line.
   - **Note:** By entering a value, you can prevent the triggering of multiple alarm events by objects that are constantly moving onto and away from the line.
4. In the *Direction* list, select the direction an object must cross the line to trigger an alarm.
   - **Forward:** An object triggers an alarm if the line is crossed according to the direction of the arrow in the graphic display.
   - **Backward:** An object triggers an alarm if the line is crossed against the direction.
   - **Any:** An object triggers an alarm if the line is crossed independently of the direction. If necessary, enter the time for each line.
5. In the *Intersection trigger* list, select the object trigger.
   - **Object center:** An object generates an alarm if the center of the object is inside the sensitive area.
– **Object base point:** An object generates an alarm if the base point of the object is inside the sensitive area.

**Define the Trigger page**
This step is only displayed if at least two lines are used for this task.
1. Select whether an object must cross only one of the lines or all lines to trigger an alarm.
2. Select the **within the time span [s]:** check box and enter a minimum and a maximum time if an object must cross the lines within a pre-defined time span before it triggers an alarm.

**Filter by Object Class page**
Limit the object classes that trigger an alarm.
- Select the desired check boxes (*Upright persons, Bikes, Cars, Trucks*).

**Approximation page**
Define approximations for the different object properties. You can adopt these values as the basis for the settings in the next step.
1. Click a moving object in the camera image. The values for object size, aspect ratio, speed and direction are displayed for the marked object. The colors of the object are also displayed.
   **Note:** The properties of an object are always changing. You adopt the properties of the object at the time of clicking.
2. Click the **Apply values** check box if you want to use the properties of the marked object.
3. Move the **Precision** slider of each property to define how exactly they must correspond for an object to be detected.
   The further to the right the slider is set, the more accurate the description of the property of the searched object that is to trigger an alarm. Slider set to the left, property is ignored and the value is not adopted in the next step.

**Filter by Object Conditions page**
Limit the properties of an object that triggers an alarm event. Objects that do not correspond to the properties specified here do not trigger an alarm event.
1. In the **Object Area [m²]** box, enter a minimum and a maximum value for the size.
2. In the **Aspect Ratio V/H** box, enter a minimum and a maximum value or select a rectangle in the camera image and change the size by dragging a node.
3. In the **Speed [km/h]** box, enter a minimum and a maximum value for the speed.
4. In the **Direction 1 [°] / Direction 2 [°]** boxes, enter a minimum and a maximum value (angle) to define the directions of a moving object. Only flows moving in these directions will trigger an alarm event.
   The directions are displayed as yellow circle segments in the camera image.
   You can also define the direction as follows:
   – Place the pointer in the yellow circle segment, press and hold the mouse button, then turn the segment.
   – Place the pointer over one of the edges of the yellow circle segment, press and hold the mouse button, then move the edge.

**Filter by Object Colors page**
Describe the color property of the searched object.
1. Move the slider to select the degree of brightness for the colors.
2. Select up to five 5 colors for the search. To do this, select a square, then click the desired color segment.
3. Move the **Precision** slider to determine how accurately the colors must match the object colors.
4. If necessary delete a selected color. To do this, select a square, then click Clear. If there are colors to the right of the deleted position, then they will move up automatically and receive a higher proportion of the object's color properties.

- Color, page 30

9.1.4 Configuring the Loitering task

In Configuration Manager: VCA tab > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > Tasks tab

In Web browser: Alarm > VCA > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > Configuration button > Tasks tab

This task generates an alarm event if an object only moves slightly within a certain area for a specified period. The area is defined by a field in the camera image.

**Note:** This task can be used for Intelligent Tracking.

To select the task:
2. On the Create a Task page, select Loitering, then click OK.

**Define the Field page**
1. Select a field from the list or create a new one.
   To create a new field, click into the camera image to start with the first corner of the field, then click again for each corner. Finish the field by double-clicking.
   **Note:** You can also select Whole screen or edit an existing field.
2. In the Debounce time [s] box, enter the minimum time that an object must remain within the field before it triggers an alarm. To do this, select the field in the camera image first, then enter the value. If necessary, enter the time for each field.
   **Note:** By entering a value, you can prevent the triggering of multiple alarm events by objects that are constantly moving toward and away from the boundary of the field.
3. In the Intersection trigger list, select the object trigger.
   - **Object center:** An object generates an alarm if the center of the object is inside the sensitive area.
   - **Edge of box:** An object generates an alarm if one of the edges of the virtual frame around the object is inside the sensitive area.
   - **Complete box:** An object generates an alarm if the virtual frame around the object is completely inside the sensitive area.
   - **Object base point:** An object generates an alarm if the base point of the object is inside the sensitive area.

**Define the Trigger page**
Define the virtual circle around the object and time span. An alarm event is generated if an object remains longer in this virtual circle.
1. In the Radius [m] box, enter the enter the loitering radius.
2. In the Time [s] box, enter the time in seconds.

**Filter by Object Class page**
Limit the object classes that trigger an alarm.
- Select the desired check boxes (Upright persons, Bikes, Cars, Trucks).
**Approximation page**

Define approximations for the different object properties. You can adopt these values as the basis for the settings in the next step.

1. Click a moving object in the camera image. The values for object size, aspect ratio, speed and direction are displayed for the marked object. The colors of the object are also displayed.
   
   **Note:** The properties of an object are always changing. You adopt the properties of the object at the time of clicking.

2. Click the *Apply values* check box if you want to use the properties of the marked object.

3. Move the *Precision* slider of each property to define how exactly they must correspond for an object to be detected.
   
   The further to the right the slider is set, the more accurate the description of the property of the searched object that is to trigger an alarm. Slider set to the left, property is ignored and the value is not adopted in the next step.

**Filter by Object Conditions page**

Limit the properties of an object that triggers an alarm event. Objects that do not correspond to the properties specified here do not trigger an alarm event.

1. In the *Object Area [m²]* box, enter a minimum and a maximum value for the size.

2. In the *Aspect Ratio V/H* box, enter a minimum and a maximum value or select a rectangle in the camera image and change the size by dragging a node.

3. In the *Speed [km/h]* box, enter a minimum and a maximum value for the speed.

4. In the *Direction 1 [°] / Direction 2 [°]* boxes, enter a minimum and a maximum value (angle) to define the directions of a moving object. Only flows moving in these directions will trigger an alarm event.
   
   The directions are displayed as yellow circle segments in the camera image.
   
   You can also define the direction as follows:
   
   - Place the pointer in the yellow circle segment, press and hold the mouse button, then turn the segment.
   
   - Place the pointer over one of the edges of the yellow circle segment, press and hold the mouse button, then move the edge.

**Filter by Object Colors page**

Describe the color property of the searched object.

1. Move the slider to select the degree of brightness for the colors.

2. Select up to five colors for the search. To do this, select a square, then click the desired color segment.

3. Move the *Precision* slider to determine how accurately the colors must match the object colors.

4. If necessary delete a selected color. To do this, select a square, then click *Clear*. If there are colors to the right of the deleted position, then they will move up automatically and receive a higher proportion of the object's color properties.

9.1.5 Configuring the Condition change task

- in Configuration Manager: VCA tab > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > Tasks tab
- in Web browser: Alarm > VCA > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > Configuration button > Tasks tab

This task generates an alarm event if the properties changes for a detected object within a specified time span:

**Note:** This task can be used for Intelligent Tracking.

To select the task:

1. On the Surveillance Tasks page, click **New**.
2. On the Create a Task page, select **Condition change**, then click **OK**.

**Filter by Object Conditions page**

Define individual properties, such as the size, aspect ratio, speed and direction, that an object must have in its initial state to be detected.

1. In the **Object Area [m²]** box, enter a minimum and a maximum value for the size.
2. In the **Aspect Ratio V/H** box, enter a minimum and a maximum value or select a rectangle in the camera image and change the size by dragging a node.
3. In the **Speed [km/h]** box, enter a minimum and a maximum value.
4. In the **Direction 1 [°] / Direction 2 [°]** boxes, enter a minimum and a maximum value (angle) to define the directions of a moving object. Only flows moving in these directions will trigger an alarm event.

The directions are displayed as yellow circle segments in the camera image.

You can also define the direction as follows:

- Place the pointer in the yellow circle segment, press and hold the mouse button, then turn the segment.
- Place the pointer over one of the edges of the yellow circle segment, press and hold the mouse button, then move the edge.

**Specify the Transition page**

Select the values that trigger an alarm when the initial state changes.

- Enter the values for **Object Area [m²]**, **Aspect Ratio V/H**, **Speed [km/h]**, **Direction 1 [°]** / **Direction 2 [°]**.

**Define the Time Span page**

Here you can limit the time span in which the conditions must change.

The time span will only be analyzed when you activate this option. If this option is not activated, respective changes in an object property will trigger an alarm event regardless of the length of time that has passed.

1. Select the **Conditions must change within the time span [s]**: check box.
2. Enter a minimum and maximum value in seconds.

**Define the Field page**

You can limit the detection to a specific area. The area is defined by a field in the camera image.

1. Select a field from the list or create a new one.
   - To create a new field, click into the camera image to start with the first corner of the field, then click again for each corner. Finish the field by double-clicking.
   
   **Note:** You can also select **Whole screen** or edit an existing field.
2. In the **Debounce time [s]** box, enter the minimum time that an object must remain within the field before it triggers an alarm. To do this, select the field in the camera image first, then enter the value. If necessary, enter the time for each field.

   **Note:** By entering a value, you can prevent the triggering of multiple alarm events by objects that are constantly moving toward and away from the boundary of the field.

3. In the **Intersection trigger** list, select the object trigger.
   - **Object center:** An object generates an alarm if the center of the object is inside the sensitive area.
   - **Edge of box:** An object generates an alarm if one of the edges of the virtual frame around the object is inside the sensitive area.
   - **Complete box:** An object generates an alarm if the virtual frame around the object is completely inside the sensitive area.
   - **Object base point:** An object generates an alarm if the base point of the object is inside the sensitive area.

**Filter by Object Class page**

Limit the object classes that trigger an alarm.
- Select the desired check boxes *(Upright persons, Bikes, Cars, Trucks).*

### 9.1.6 Configuring the Following route task

**in Configuration Manager:** VCA tab > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > Tasks tab

**in Web browser:** Alarm > VCA > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > Configuration button > Tasks tab

This task generates an alarm event if an object moves along a certain route. A route is surrounded by a virtual tolerance area.

**Note:** This task can be used for Intelligent Tracking.

**Notice!**

This task is typically used in the Video Client program for forensic search. For example, persons who have taken a certain route are detected this way.

To select the task:

1. On the **Surveillance Tasks** page, click **New**.
2. On the **Create a Task** page, select **Following route**, then click **OK**.

**Define the Route page**

1. In the list, select one of the routes that have already been created or click a route in the camera image.

   **Note:** You can also create a new route or edit an existing one.

2. In the **Min. match [%]** box, enter the percentage of the total distance an object must move along the route to trigger an alarm.
The value indicates the overall proportion of the route. An object must not necessarily cover this percentage of a section in a single stage in order to trigger an alarm event.

3. In the **Max. gap [%]** box, enter the value for the largest gap in percent of the total distance. This gap allows the object to leave and re-enter the route and generating an alarm event. The object can leave the route several times.

4. In the **Direction** list, select the direction an object must move to trigger an alarm.
   - **Forward**: Triggers an alarm if an object follows the arrows of the route displayed in the camera image.
   - **Backward**: Triggers an alarm if an object moves in the opposite direction of the arrows.
   - **Any**: Triggers an alarm independently of the direction.

5. In the **Intersection trigger** list, select the object trigger.
   - **Object center**: An object generates an alarm if the center of the object is inside the route.
   - **Edge of box**: An object generates an alarm if one of the edges of the virtual frame around the object is inside the route.
   - **Complete box**: An object generates an alarm if the virtual frame around the object is completely inside the route.
   - **Object base point**: An object generates an alarm if the base point of the object is inside the route.

**Filter by Object Class page**
Limit the object classes that trigger an alarm.
- Select the desired check boxes (Upright persons, Bikes, Cars, Trucks).

**Approximation page**
Define approximations for the different object properties. You can adopt these values as the basis for the settings in the next step.

1. Click a moving object in the camera image. The values for object size, aspect ratio, speed and direction are displayed for the marked object. The colors of the object are also displayed.
   - **Note**: The properties of an object are always changing. You adopt the properties of the object at the time of clicking.

2. Click the **Apply values** check box if you want to use the properties of the marked object.

3. Move the **Precision** slider of each property to define how exactly they must correspond for an object to be detected.
   - The further to the right the slider is set, the more accurate the description of the property of the searched object that is to trigger an alarm. Slider set to the left, property is ignored and the value is not adopted in the next step.

**Filter by Object Conditions page**
Limit the properties of an object that triggers an alarm event. Objects that do not correspond to the properties specified here do not trigger an alarm event.

1. In the **Object Area [m²]** box, enter a minimum and a maximum value for the size.

2. In the **Aspect Ratio V/H** box, enter a minimum and a maximum value or select a rectangle in the camera image and change the size by dragging a node.

3. In the **Speed [km/h]** box, enter a minimum and a maximum value for the speed.

4. In the **Direction 1 [°] / Direction 2 [°]** boxes, enter a minimum and a maximum value (angle) to define the directions of a moving object. Only flows moving in these directions will trigger an alarm event.
   - The directions are displayed as yellow circle segments in the camera image.
   - You can also define the direction as follows:
     - Place the pointer in the yellow circle segment, press and hold the mouse button, then turn the segment.
Place the pointer over one of the edges of the yellow circle segment, press and hold the mouse button, then move the edge.

**Filter by Object Colors page**
Describe the color property of the searched object.

1. Move the slider to select the degree of brightness for the colors.
2. Select up to five 5 colors for the search. To do this, select a square, then click the desired color segment.
3. Move the **Precision** slider to determine how accurately the colors must match the object colors.
4. If necessary delete a selected color. To do this, select a square, then click **Clear**. If there are colors to the right of the deleted position, then they will move up automatically and receive a higher proportion of the object's color properties.

### 9.1.7 Configuring the Tampering task

- **in Configuration Manager:** VCA tab > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > Tasks tab
- **in Web browser:** Alarm > VCA > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > Configuration button > Tasks tab

This task generates an alarm event if it must be assumed that the video source (camera) has been tampered with.

Here, you can only activate the filter for the relevant events. You cannot alter the settings for tamper detection. Only the settings selected on the VCA start page can be activated here.

To select the task:

1. On the **Surveillance Tasks** page, click **New**.
2. On the **Create a Task** page, select **Tampering**, then click **OK**.

**Define the Trigger page**

One of the activated events must occur to trigger an alarm event.

- Select the corresponding event.

**Global change**
The global change, as set with the **Global change** slider on the standard configuration page, should trigger an alarm.

**Scene too bright**
Tampering associated with exposure to extreme light (for instance, shining a flashlight directly on the lens) should trigger an alarm. The average brightness of the scene provides a basis for recognition.

**Scene too dark**
Tampering associated with covering the lens should trigger an alarm. The average brightness of the scene provides a basis for recognition.

**Reference check**
A deviation from the reference image on the VCA start page should trigger an alarm.
9.1.8 Configuring the Removed object task

in Configuration Manager: VCA tab > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > Tasks tab

in Web browser: Alarm > VCA > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > Configuration button > Tasks tab

This task generates an alarm event if an object is detected as removed in a certain area (for example, due to theft). The area is defined by a field in the camera image.

Notice!
For CPP6 cameras the idle and removed object detection is deactivated in areas with strong motion (bushes or trees that are moving in the wind, for example). If you want to detect idle or removed objects in this areas, under Metadata Generation > Tracking, deactivate the Noise suppression check box. This will also increase the amount of false alarms.

To select the task:

2. On the Create a Task page, select Removed object, then click OK.

Define the Field page

1. Select a field from the list or create a new one.

To create a new field, click into the camera image to start with the first corner of the field, then click again for each corner. Finish the field by double-clicking.

Note: You can also select Whole screen or edit an existing field.

2. In the Intersection trigger list, select the object trigger.
   - Object center: An object generates an alarm if the center of the object is inside the sensitive area.
   - Edge of box: An object generates an alarm if one of the edges of the virtual frame around the object is inside the sensitive area.
   - Complete box: An object generates an alarm if the virtual frame around the object is completely inside the sensitive area.
   - Object base point: An object generates an alarm if the base point of the object is inside the sensitive area.

Filter by Object Type page

Select the type of removed objects that should trigger an alarm event.

1. Select the object type.
   - All removed objects: Generates an alarm for all objects that are removed in the sensitive area of the camera image (all started and taken objects).
     Note: An object is assumed to have been removed if changes are detected in the background following motion within an image.
   - Only started objects: Generates an alarm event as soon as an idle object (a car, for example) in the sensitive area starts moving.
   - Only taken objects: Generates an alarm event as soon as an idle object (a suitcase, for example) in the sensitive area is being taken away by a tracked moving object (a person, for example).
     Note: The time span the object must remain removed is displayed in the Taken objects box.

Filter by Object Class page

Limit the object classes that trigger an alarm.

- Select the desired check boxes (Upright persons, Bikes, Cars, Trucks).
Approximation page
Define approximations for the different object properties. You can adopt these values as the basis for the settings in the next step.

1. Click a moving object in the camera image. The values for object size, aspect ratio, speed and direction are displayed for the marked object. The colors of the object are also displayed.
   **Note:** The properties of an object are always changing. You adopt the properties of the object at the time of clicking.

2. Click the Apply values check box if you want to use the properties of the marked object.

3. Move the Precision slider of each property to define how exactly they must correspond for an object to be detected.
   The further to the right the slider is set, the more accurate the description of the property of the searched object that is to trigger an alarm. Slider set to the left, property is ignored and the value is not adopted in the next step.

Filter by Object Conditions page
Limit the properties of an object that triggers an alarm event. Objects that do not correspond to the properties specified here do not trigger an alarm event.

1. In the **Object Area [m²]** box, enter a minimum and a maximum value for the size.

2. In the **Aspect Ratio V/H** box, enter a minimum and a maximum value or select a rectangle in the camera image and change the size by dragging a node.

3. In the **Speed [km/h]** box, enter a minimum and a maximum value for the speed.

4. In the **Direction 1 [°]** / **Direction 2 [°]** boxes, enter a minimum and a maximum value (angle) to define the directions of a moving object. Only flows moving in these directions will trigger an alarm event.
   The directions are displayed as yellow circle segments in the camera image.
   You can also define the direction as follows:
   - Place the pointer in the yellow circle segment, press and hold the mouse button, then turn the segment.
   - Place the pointer over one of the edges of the yellow circle segment, press and hold the mouse button, then move the edge.

Filter by Object Colors page
Describe the color property of the searched object.

1. Move the slider to select the degree of brightness for the colors.

2. Select up to five 5 colors for the search. To do this, select a square, then click the desired color segment.

3. Move the Precision slider to determine how accurately the colors must match the object colors.

4. If necessary delete a selected color. To do this, select a square, then click Clear. If there are colors to the right of the deleted position, then they will move up automatically and receive a higher proportion of the object's color properties.

9.1.9 Configuring the Idle object task

- in Configuration Manager: VCA tab > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > Tasks tab
- in Web browser: Alarm > VCA > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > Configuration button > Tasks tab

This task generates an alarm event if an object is detected as idle or inserted in a certain area (for example, a piece of luggage without an owner). The area is highlighted by a field in the camera image.

**Notice!**

For CPP6 cameras the idle and removed object detection is deactivated in areas with strong motion (bushes or trees that are moving in the wind, for example). If you want to detect idle or removed objects in this areas, under Metadata Generation > Tracking, deactivate the Noise suppression check box. This will also increase the amount of false alarms.

To select the task:
2. On the Create a Task page, select Idle object, then click OK.

**Define the Field page**

1. Select a field from the list or create a new one.
   - To create a new field, click into the camera image to start with the first corner of the field, then click again for each corner. Finish the field by double-clicking.
   - **Note:** You can also select Whole screen or edit an existing field.
2. In the Intersection trigger list, select the object trigger.
   - **Object center:** An object generates an alarm if the center of the object is inside the sensitive area.
   - **Edge of box:** An object generates an alarm if one of the edges of the virtual frame around the object is inside the sensitive area.
   - **Complete box:** An object generates an alarm if the virtual frame around the object is completely inside the sensitive area.
   - **Object base point:** An object generates an alarm if the base point of the object is inside the sensitive area.

**Filter by Object Type page**

Select the type of idle objects that should trigger an alarm event.

1. Select the object type.
   - **All idle objects:** Generates an alarm for all objects that remain idle in the sensitive area of the camera image (all stopped and placed objects).
   - **Only stopped objects:** Generates an alarm event if a tracked and moving object (a car, for example) stops in the sensitive area.
     - **Note:** The time span the object must remain idle is displayed in the Stopped objects box.
   - **Only placed objects:** Generates an alarm event if a tracked object (a person, for example) places an object (a suitcase, for example) in the sensitive area of the camera image.
     - **Note:** The time span the object must remain idle is displayed in the Placed objects box.

**Filter by Object Class page**

Limit the object classes that trigger an alarm.

- Select the desired check boxes (Upright persons, Bikes, Cars, Trucks).
Approximation page
Define approximations for the different object properties. You can adopt these values as the basis for the settings in the next step.

1. Click a moving object in the camera image. The values for object size, aspect ratio, speed and direction are displayed for the marked object. The colors of the object are also displayed.
   **Note:** The properties of an object are always changing. You adopt the properties of the object at the time of clicking.
2. Click the **Apply values** check box if you want to use the properties of the marked object.
3. Move the **Precision** slider of each property to define how exactly they must correspond for an object to be detected. The further to the right the slider is set, the more accurate the description of the property of the searched object that is to trigger an alarm. Slider set to the left, property is ignored and the value is not adopted in the next step.

9.1.10 Configuring the Entering field task

- in Configuration Manager: VCA tab > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > Tasks tab

- in Web browser: Alarm > VCA > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > Configuration button > Tasks tab

This task generates an alarm event if an object that was previously detected outside a field crosses the field boundary to enter the field.

**Note:** This task can be used for Intelligent Tracking.

To select the task:
2. On the Create a Task page, select Entering field, then click OK.

**Define the Field page**

1. Select a field from the list or create a new one.
   - To create a new field, click into the camera image to start with the first corner of the field, then click again for each corner. Finish the field by double-clicking.
   - **Note:** You can also select Whole screen or edit an existing field.

2. In the Debounce time \([s]\) box, enter the minimum time that an object must remain within the field before it triggers an alarm. To do this, select the field in the camera image first, then enter the value. If necessary, enter the time for each field.
   - **Note:** By entering a value, you can prevent the triggering of multiple alarm events by objects that are constantly moving toward and away from the boundary of the field.

3. In the Intersection trigger list, select the object trigger.
   - **Object center:** An object generates an alarm if the center of the object is inside the sensitive area.
   - **Edge of box:** An object generates an alarm if one of the edges of the virtual frame around the object is inside the sensitive area.
   - **Complete box:** An object generates an alarm if the virtual frame around the object is completely inside the sensitive area.
   - **Object base point:** An object generates an alarm if the base point of the object is inside the sensitive area.

**Filter by Object Class page**

Limit the object classes that trigger an alarm.

9.1.11 Configuring the Leaving field task

**in Configuration Manager:** VCA tab > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > **Tasks** tab

**in Web browser:** Alarm > VCA > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > **Configuration** button > **Tasks** tab

This task generates an alarm event if an object that was previously detected inside a field crosses the field boundary to leave the field.

**Note:** This task can be used for Intelligent Tracking.
To select the task:
1. On the **Surveillance Tasks** page, click **New**.
2. On the **Create a Task** page, select **Leaving field**, then click **OK**.
Define the Field page
1. Select a field from the list or create a new one.
   To create a new field, click into the camera image to start with the first corner of the field, then click again for each corner. Finish the field by double-clicking.
   Note: You can also select Whole screen or edit an existing field.
2. In the Debounce time [s] box, enter the minimum time that an object must remain within the field before it triggers an alarm. To do this, select the field in the camera image first, then enter the value. If necessary, enter the time for each field.
   Note: By entering a value, you can prevent the triggering of multiple alarm events by objects that are constantly moving toward and away from the boundary of the field.
3. In the Intersection trigger list, select the object trigger.
   - Object center: An object generates an alarm if the center of the object is inside the sensitive area.
   - Edge of box: An object generates an alarm if one of the edges of the virtual frame around the object is inside the sensitive area.
   - Complete box: An object generates an alarm if the virtual frame around the object is completely inside the sensitive area.
   - Object base point: An object generates an alarm if the base point of the object is inside the sensitive area.

Notice!
When configuring the Leaving field task, note that the alarm is generated as soon as the object is no longer in the field. Thus the different object triggers behave as follows:
The object trigger Edge of box generates an alarm event if no edge of the object is any longer within the field and thus the object is completely outside the field.
The object trigger Complete box generates an alarm event as soon as any part of the virtual frame around the object is outside the field.

Filter by Object Class page
Limit the object classes that trigger an alarm.
   - Select the desired check boxes (Upright persons, Bikes, Cars, Trucks).

Approximation page
Define approximations for the different object properties. You can adopt these values as the basis for the settings in the next step.
1. Click a moving object in the camera image. The values for object size, aspect ratio, speed and direction are displayed for the marked object. The colors of the object are also displayed.
   Note: The properties of an object are always changing. You adopt the properties of the object at the time of clicking.
2. Click the Apply values check box if you want to use the properties of the marked object.
3. Move the Precision slider of each property to define how exactly they must correspond for an object to be detected.
   The further to the right the slider is set, the more accurate the description of the property of the searched object that is to trigger an alarm. Slider set to the left, property is ignored and the value is not adopted in the next step.

Filter by Object Conditions page
Limit the properties of an object that triggers an alarm event. Objects that do not correspond to the properties specified here do not trigger an alarm event.
1. In the Object Area [m²] box, enter a minimum and a maximum value for the size.
2. In the **Aspect Ratio V/H** box, enter a minimum and a maximum value or select a rectangle in the camera image and change the size by dragging a node.

3. In the **Speed [km/h]** box, enter a minimum and a maximum value for the speed.

4. In the **Direction 1 [°] / Direction 2 [°]** boxes, enter a minimum and a maximum value (angle) to define the directions of a moving object. Only flows moving in these directions will trigger an alarm event.

   The directions are displayed as yellow circle segments in the camera image.

   You can also define the direction as follows:
   - Place the pointer in the yellow circle segment, press and hold the mouse button, then turn the segment.
   - Place the pointer over one of the edges of the yellow circle segment, press and hold the mouse button, then move the edge.

**Filter by Object Colors page**

Describe the color property of the searched object.

1. Move the slider to select the degree of brightness for the colors.

2. Select up to five 5 colors for the search. To do this, select a square, then click the desired color segment.

3. **Move the Precision** slider to determine how accurately the colors must match the object colors.

4. If necessary delete a selected color. To do this, select a square, then click **Clear**. If there are colors to the right of the deleted position, then they will move up automatically and receive a higher proportion of the object's color properties.

### 9.1.12 Configuring the Similarity search task

**in Configuration Manager:** VCA tab > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > Tasks tab

**in Web browser:** Alarm > VCA > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > Configuration button > Tasks tab

This task generates an alarm event if an object is detected that is similar to a previously marked object.

**Note:** This task can be used for Intelligent Tracking.

**Notice!**

This task is typically used in the Video Client program for forensic search. For example, persons who are similar to a certain person are detected this way.

To select the task:

1. On the **Surveillance Tasks** page, click **New**.
2. On the **Create a Task** page, select **Similarity search**, then click **OK**.
Approximation page

1. Click a moving object in the camera image. The values for object size, aspect ratio, speed and direction are displayed for the marked object. The colors of the object are also displayed. The object is marked with a yellow triangle.

Note: The properties of an object are always changing. You adopt the properties of the object at the time of clicking.

2. Move the Precision slider of each property to define how exactly they must correspond for an object to be detected.

The further to the right the slider is set, the more accurate the description of the property of the searched object that is to trigger an alarm. Slider set to the left, property is ignored and the value is not adopted in the next step.

– Conditions in tasks, page 28

9.1.13 Configuring the Crowd detection task

Configure in Configuration Manager: VCA tab > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > Tasks tab

Configure in Web browser: Alarm > VCA > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > Configuration button > Tasks tab

This task generates an alarm event if a number of objects are located within a certain area.

The area is defined by a crowd field in the camera image.

To use the Crowd detection functionality, first create a reference image of the background without people present on the standard VCA configuration page. The reference image must depict the current background captured by the camera. Create a new reference picture if the background has changed.

To select the task:

2. On the Create a Task page, select Crowd detection, then click OK.

Filter by Crowd Field Properties page

1. In the Select a crowd field: list, select one of the crowd fields that have already been created.

Note: You cannot create or edit a crowd field here.

2. Move the Crowd density slider to define how dense a crowd must be to be detected as a crowd.

The equivalent on the scale is different according to the settings and conditions of each system. Determine a meaningful threshold value for triggering an alarm for your setup by testing.

3. In the Debounce time [s] box, enter the minimum time that a crowd must be detected within the field before it triggers an alarm

4. In the Smoothing time [s] box, enter the minimum time after which an alarm is triggered if the average crowd density over this period exceeds the value set by the Crowd density slider.

See also
– Configuring the crowd fields, page 73

9.1.14 Configuring the Counter task

Configure in Configuration Manager: VCA tab > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > Tasks tab
To count people, use a BEV camera perspective for best performance. Calibrate the camera and set the **3D people tracking** mode.

To select the task:
1. On the **Surveillance Tasks** page, click **New**.
2. On the **Create a Task** page, select **Counter**, then click **OK**.

**Define the Lines page**
1. From the list, select one of the lines that have already been created or click a line in the camera image.
   - **Note:** You can also create a new line or edit an existing one.
2. Select a second and a third line, if necessary.
3. In the **Debounce time [s]** box, enter the minimum time that an object must be observed first before crossing the line and then also after crossing the line to trigger an alarm. To do this, select the line in the camera image first, then enter the value. If necessary, enter the time for each line.
   - **Note:** By entering a value, you can prevent the triggering of multiple alarm events by objects that are constantly moving onto and away from the line.
4. In the **Direction** list, select the direction an object must cross the line to trigger an alarm.
   - **Forward:** An object triggers an alarm if the line is crossed according to the direction of the arrow in the graphic display.
   - **Backward:** An object triggers an alarm if the line is crossed against the direction.
   - **Any:** An object triggers an alarm if the line is crossed independently of the direction.
   - If necessary, enter the time for each line.
5. In the **Intersection trigger** list, select the object trigger.
   - **Object center:** An object generates an alarm if the center of the object crosses the line.
   - **Edge of box:** An object generates an alarm if one of the edges of the virtual frame around the object crosses the line.
   - **Complete box:** An object generates an alarm if the virtual frame around the object crosses completely the line.
   - **Object base point:** An object generates an alarm if the base point of the object crosses the line.

**Define the Counter Limit and Alarm page**
1. In the **Limit** box enter a maximum value.
2. Click **Restart counting** or **Stop counting**.
   - **Restart counting:** The system restarts counting after the maximum value is reached.
   - **Stop counting:** The system stops counting if the maximum value is reached.
3. Select the **Alarm on overflow** check box to trigger an alarm event if the limit is reached.

**Filter by Object Class page**
Limit the object classes that trigger an alarm.
- Select the desired check boxes (**Upright persons**, **Bikes**, **Cars**, **Trucks**).
**Approximation page**
Define approximations for the different object properties. You can adopt these values as the basis for the settings in the next step.

1. Click a moving object in the camera image. The values for object size, aspect ratio, speed and direction are displayed for the marked object. The colors of the object are also displayed.
   **Note:** The properties of an object are always changing. You adopt the properties of the object at the time of clicking.
2. Click the **Apply values** check box if you want to use the properties of the marked object.
3. Move the **Precision** slider of each property to define how exactly they must correspond for an object to be detected.
   The further to the right the slider is set, the more accurate the description of the property of the searched object that is to trigger an alarm. Slider set to the left, property is ignored and the value is not adopted in the next step.

**Filter by Object Conditions page**
Limit the properties of an object that triggers an alarm event. Objects that do not correspond to the properties specified here do not trigger an alarm event.

1. In the **Object Area [m²]** box, enter a minimum and a maximum value for the size.
2. In the **Aspect Ratio V/H** box, enter a minimum and a maximum value or select a rectangle in the camera image and change the size by dragging a node.
3. In the **Speed [km/h]** box, enter a minimum and a maximum value for the speed.
4. In the **Direction 1 [°] / Direction 2 [°]** boxes, enter a minimum and a maximum value (angle) to define the directions of a moving object. Only flows moving in these directions will trigger an alarm event.
   The directions are displayed as yellow circle segments in the camera image.
   You can also define the direction as follows:
   – Place the pointer in the yellow circle segment, press and hold the mouse button, then turn the segment.
   – Place the pointer over one of the edges of the yellow circle segment, press and hold the mouse button, then move the edge.

**Filter by Object Colors page**
Describe the color property of the searched object.

1. Move the slider to select the degree of brightness for the colors.
2. Select up to five 5 colors for the search. To do this, select a square, then click the desired color segment.
3. Move the **Precision** slider to determine how accurately the colors must match the object colors.
4. If necessary delete a selected color. To do this, select a square, then click **Clear**. If there are colors to the right of the deleted position, then they will move up automatically and receive a higher proportion of the object’s color properties.

**See also**
- **Object triggers, page 21**

9.1.15 Configuring the Occupancy task

- In Configuration Manager: VCA tab > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > Tasks tab
- In Web browser: Alarm > VCA > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > Configuration button > Tasks tab

This task generates an alarm event if a certain number of objects are inside a field. In addition, this task sets up a counter with the current number of objects in the field.

Notice! This task is useful for Queue Management.

To select the task:
2. On the Create a Task page, select Occupancy, then click OK.

Define the Field page
1. Select a field from the list or create a new one.
   - To create a new field, click into the camera image to start with the first corner of the field, then click again for each corner. Finish the field by double-clicking.
   - Note: You can also select Whole screen or edit an existing field.
2. In the Debounce time [s] box, enter the minimum time that an object must remain within the field before it triggers an alarm. To do this, select the field in the camera image first, then enter the value. If necessary, enter the time for each field.
   - Note: By entering a value, you can prevent the triggering of multiple alarm events by objects that are constantly moving toward and away from the boundary of the field.
3. In the Intersection trigger list, select the object trigger.
   - Object center: An object generates an alarm if the center of the object is inside the sensitive area.
   - Edge of box: An object generates an alarm if one of the edges of the virtual frame around the object is inside the sensitive area.
   - Complete box: An object generates an alarm if the virtual frame around the object is completely inside the sensitive area.
   - Object base point: An object generates an alarm if the base point of the object is inside the sensitive area.

Occupancy alarm page
1. Select the Alarm on overcrowding check box if the system must generate an alarm event depending from the minimum number of objects inside a field.
2. In the Critical value box, enter the minimum number of objects that must be inside a field to generate an alarm.

Filter by Object Class page
Limit the object classes that trigger an alarm.
- Select the desired check boxes (Upright persons, Bikes, Cars, Trucks).

Approximation page
Define approximations for the different object properties. You can adopt these values as the basis for the settings in the next step.
1. Click a moving object in the camera image. The values for object size, aspect ratio, speed and direction are displayed for the marked object. The colors of the object are also displayed.
   **Note:** The properties of an object are always changing. You adopt the properties of the object at the time of clicking.

2. Click the **Apply values** check box if you want to use the properties of the marked object.

3. Move the **Precision** slider of each property to define how exactly they must correspond for an object to be detected.
   The further to the right the slider is set, the more accurate the description of the property of the searched object that is to trigger an alarm. Slider set to the left, property is ignored and the value is not adopted in the next step.

**Filter by Object Conditions page**
Limit the properties of an object that triggers an alarm event. Objects that do not correspond to the properties specified here do not trigger an alarm event.

1. In the **Object Area [m²]** box, enter a minimum and a maximum value for the size.
2. In the **Aspect Ratio V/H** box, enter a minimum and a maximum value or select a rectangle in the camera image and change the size by dragging a node.
3. In the **Speed [km/h]** box, enter a minimum and a maximum value.
4. In the **Direction 1 [°]** / **Direction 2 [°]** boxes, enter a minimum and a maximum value (angle) to define the directions of a moving object. Only flows moving in these directions will trigger an alarm event.
   The directions are displayed as yellow circle segments in the camera image.
   You can also define the direction as follows:
   - Place the pointer in the yellow circle segment, press and hold the mouse button, then turn the segment.
   - Place the pointer over one of the edges of the yellow circle segment, press and hold the mouse button, then move the edge.

**Filter by Object Colors page**
Describe the color property of the searched object.

1. Move the slider to select the degree of brightness for the colors.
2. Select up to five colors for the search. To do this, select a square, then click the desired color segment.
3. Move the **Precision** slider to determine how accurately the colors must match the object colors.
4. If necessary delete a selected color. To do this, select a square, then click **Clear**. If there are colors to the right of the deleted position, then they will move up automatically and receive a higher proportion of the object’s color properties.

### 9.2 Metadata generation

**Notice!**
This tab provides access to basic settings that you can adapt for performance optimization. The settings and values defined here are valid for all tasks.
9.2.1 Calibrating the camera

- in Configuration Manager: VCA tab > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > Metadata Generation tab > Calibration tab

- in Web browser: Alarm > VCA > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > Configuration button > Metadata Generation tab > Calibration tab

Notice!
This page is not available on panoramic cameras. In case of a panoramic camera, calibrate the camera under Installer Menu > Positioning.

A camera is calibrated by assuming that the ground is horizontal and completely flat, and then teaching the camera its position and field of view in relation to the ground plane. Camera sensor size and focal length of the lens determine how wide and far the camera can basically see with sufficient resolution. Elevation above ground plane, together with the relative camera angles to the ground plane (tilt and roll angle) then determines the actual field of view of the camera.

Bosch IP cameras support you in calibrating the camera by providing all information known by the camera itself. And in CPP7 cameras an additional sensor determines the camera angles. Thus, the following values - needed for calibration - are set automatically for the different camera types:
- Tilt and roll angle:
  - For all AUTODOME, MIC and CPP7 cameras
- Focal length:
  - For all AUTODOME, MIC and FLEXIDOME cameras
- Sensor size:
  - For all Bosch IP cameras

Therefore for AUTODOME, MIC, FLEXIDOME and CPP7 cameras, only the height of the camera above the ground must be set manually. If needed, you can manually overwrite of the tilt and roll angle and the focal length.

Notice!
Set the camera to its final position and the lens to its zoom factor before calibrating the camera. Any changes in the camera position or the focal length of the lens will not be updated during the VCA configuration pages are open.

For the device web page: Close the VCA configuration and open it again to obtain the values that are set automatically by the camera.

In Configuration Manager: Change to pages others then Tasks, Metadata Generation, Metadata Statistics, and then open Metadata Generation > Calibration again.

Opening the calibration page with default configuration active or camera not calibrated
In the default configuration, the camera is not calibrated. The Use camera values check box is activated, all values are displayed that are set automatically. They are fixed and changing them is deactivated. Enter all missing values, press Apply, and then save the configuration.

Opening the calibration page if camera is already calibrated and the Use camera values check box is activated
The camera values that are set automatically are displayed with updated values, though the old calibration is still active. Press Cancel to obtain the values which are used or press Apply to adjust the calibration to the updated values. Save the configuration.
Opening the calibration page if camera is already calibrated and the Use camera values check box is deactivated.

The values that are configured manually by the user are displayed. To obtain values that are set automatically, select the **Use camera values** check box, press **Apply**, and then save the configuration.

**Notice!**
Calibration status (camera calibrated / not calibrated) is shown on **Global settings**.

To overwrite the automatically set values:
- Clear the **Use camera values** check box. Entering and fixing the values thus becomes available.

To determine non-automatically set values:
1. For each value (tilt angle, roll angle, elevation, focal length) where the value is known (e.g. by measuring the elevation of the camera above the ground, or reading the focal length from the lens), select the **Fixed** check box and enter its value.
2. For any values that are still unknown, place a calibration elements on the camera image. Use these calibration elements to trace individual outlines of the displayed environment in the camera image and define the position and size of these lines and angles.
   - Click ![vertical line](image) to place a vertical line across the image. A vertical line corresponds to a line that is perpendicular to the ground plane, such as a door frame, edge of a building or a lamp post.
   - Click ![ground line](image) to place a line across the ground in the image. A line on ground corresponds to a line that is on the ground plane, such as a road marking.
   - Click ![angle](image) to place an angle on the ground in the image. The angle on ground represents an angle lying on the horizontal ground plane, such as the corner of a carpet or parking bay markings.
3. Adjust the calibration elements to the situation:
   - Enter the real size of a line or angle. To do this, select the line or angle, then enter the size in the **Size [m]** box. **Example**: You have placed a line on ground across the lower side of an automobile. You know that the automobile is 4 m long. Enter 4 m as the length of the line.
   - Adjust the position or length of a line or angle. To do this, drag the line or angle as a whole, or its end points individually, to the desired position in the camera image.
   - Remove a line or angle. To do this, select the line or angle, then click **Remove Element**.

**Note:**
- **Blue** lines indicate calibration elements added by you.
- **White** lines represent the element as it should be positioned on the camera image based on the current calibration results or the determined calibration data.
4. Click **Adapt Elements** to adapt the calibration elements to the calibration results or the calibration data.
5. Click **Calibrate**.
**Note:** Calibration is carried out automatically when the calibration elements are moved.

6. Click **Apply** to save the calibration for this image.

---

**Notice!**

If the distance to the camera (geolocation) is not relevant, it is enough to determine height and focal length in relation to each other. This allows a simple calibration by marking 2-3 persons - each with a vertical line - and setting their size. 1,80 m (71 in.) for all is sufficient. Use at least one person in the front and one person in the background of the image for best results.

---

To verify calibration:

You can verify calibration by inserting calibration elements next to objects with known dimensions.

1. Click **Verify**.
   The button changes the labeling to **Calibrate**.

2. Place elements on the camera image, as described previously.
   The dimensions of the element are displayed underneath the buttons as they are determined by the calibration. These dimensions should correspond to reality, which means that a line that is 1 m long on the captured image will be displayed as 1 m in length.

3. Click **Calibrate** to switch back to calibration mode.

**Horizon**

If the values correspond, areas on the camera image have a colored background:

- **blue:** This area corresponds to the sky; the bottom line of the blue area represents the horizon. Objects that are detected in the blue area cannot be filtered correctly by size or speed.

- **yellow:** Objects that are smaller than 2 m and are in the area underneath the horizon cannot be detected as they are too small. If you wish to detect objects in this area, you must choose a different camera location.

If the camera is installed at a relatively low height in a building, for example, this display is not required, because the entire area covered by the camera is below the horizon.

The ToolTip indicates the deviation of the elements you created from the suggested elements. The smaller this value is, the better the calibration.

**See also**

- **Calibration, page 22**

---

### 9.2.2 Configuring the global settings

- **in Configuration Manager:** VCA tab > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > Metadata Generation tab > Global Settings tab

- **in Web browser:** Alarm > VCA > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > Configuration button > Metadata Generation tab > Global Settings tab

This page allows you to enable the **Face Detection** functionality.

- Select the **Face detection** check box, if you want to store faces for recognition.

**See also**

- **Global settings, page 31**
9.2.3 Configuring the sensitive area

- In Configuration Manager: VCA tab > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > Metadata Generation tab > Sensitive Area tab
- In Web browser: Alarm > VCA > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > Configuration button > Metadata Generation tab > Sensitive Area tab

This page allows you to define insensitive areas.

Notice!
The insensitive areas (VCA Masks) do not apply for crowd density estimation.

To define insensitive areas:
1. On the VCA Masking page, click Add. An insensitive area is added to the camera image.
   Note: You can also define an insensitive area directly in the camera image. To do this, click into the camera image. Each click creates a new corner of the insensitive area. A double-click closes the insensitive area.
2. In the camera image, adjust the position and size of the insensitive area if necessary.

To remove insensitive areas:
   - On the VCA Masking page, select an insensitive area from the list or in the camera image, then click Remove.

See also
- Sensitive area, page 31

9.2.4 Configuring the tracking parameters

- In Configuration Manager: VCA tab > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > Metadata Generation tab > Tracking tab
- In Web browser: Alarm > VCA > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > Configuration button > Metadata Generation tab > Tracking tab

This page allows you to define the tracking mode and the object detection settings.

To configure the tracking parameters:
1. On the Tracking Parameters page, select the tracking type.
   - Standard tracking: Standard tracking of moving regions in the image plane. A calibration is not required. Can be used if the scene consists of multiple floors, a staircase, for example. Objects are separated if possible and shapes are automatically smoothed.
   - 3D tracking: Three-dimensional tracking of objects on the ground plane. Objects are separated if possible. Object shapes are automatically smoothed and for upright persons a 3D shape model is fitted. This improves detection and tracking in scenes with one main ground plane. A scene that consists of multiple floors or a staircase, for example, is not suitable for 3D tracking mode.
Note:

3D tracking only take effect after calibrating the camera. Calibration is required to detect and track objects on the ground plane and to classify objects by their real size. Do not use 3D tracking if camera height is below 2.50 m (recommended for optimal results: above 3 m).

- 3D people tracking:
  All objects are interpreted as persons and separated accordingly. 3D person shapes are fitted onto the persons. This feature is optimized for detecting and tracking people from above and in closed areas.

  Note:
  3D people tracking only take effect after calibrating the camera. Calibration is required to detect and track objects on the ground plane and to classify objects by their real size.

  If 3D people tracking mode is selected, the aspect ratio of a person does not change even if the person falls down or stands up. In 3D people tracking mode the person shape remains in upright position.

- Ship tracking (only for CPP6 and CPP7 cameras):
  Tracking that is optimized to detect an object above the water surface similar to watercrafts.

- Museum mode:
  Tracking that is optimized to detect any motion close to a museum exhibit and then generating an alarm event, for example, if a person is close to exhibits or is touching a painting. No separation of objects is available.

  Note: Use Museum mode in combination with the intersection trigger Edge of box.

2. Only for CPP4 cameras:
   In the Object Area [m²] box, enter the minimum size for all objects that will generate an alarm event. Objects that are smaller than the specified size will be ignored. Make sure that the value is not too large, to avoid that relevant objects are unintentionally eliminated from alarm generation.

  Note: The value is graphically displayed in the camera image by a yellow-framed square. Drag one of the blue nodes to adjust the value. The yellow square can be moved in the camera image to cover objects being used for size comparison.

3. Only for CPP6 and CPP7 cameras:
   In the Min. object area [m²] box, enter the minimum size for all objects that will generate an alarm event.

4. In the Noise suppression list, select the desired entry (Off, Medium, Strong) to improve the suppression of unwanted alarms.
   For example, alarms that are caused by:
   - Bushes or trees that are moving in the wind.
   - Any stationary object that moves slightly in camera's line of sight.
   - Low contrast shadows, reflections and illumination changes.

5. Only for CPP6 and CPP7 cameras:
   Move the Sensitivity slider to define the sensitivity.

  Note: As soon as a new object appears, video analytics considers the travelled distance and the period the new object can be observed to decide, whether it is really an object and must be added to the metadata, or whether it is only a disturbance. This decision may be delayed if noise suppression is activated and a part of the image is classified as
being noisy. Decrease the sensitivity if too many false objects occur, or increase the sensitivity if objects are missed or detected too late.

9.2.5 Configuring the idle/removed parameters

in Configuration Manager: VCA tab > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > Metadata Generation tab > Idle/Removed tab

in Web browser: Alarm > VCA > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > Configuration button > Metadata Generation tab > Idle/Removed tab

This page allows you to define the parameters of idle and removed objects.

To configure the parameters:

1. Under **Tracked Objects**, in the **Debounce time [s] (only stopped objects)** box, enter the time span a tracked and moving object must remain idle in order to be classified as stopped. Note that the tracking of this object then stops.

2. Select the **Generate 'started/stopped' metadata** check box to generate metadata as follows:
   - Started objects: Generates metadata as soon as an idle object (a car, for example) in the sensitive area starts moving.
   - Stopped objects: Generates metadata if a tracked and moving object (a car, for example) stops in the sensitive area for the defined debounce time.

3. Select the **Generate 'placed/taken' metadata** check box to generate metadata as follows:
   - Placed objects: Generates metadata if an object (a suitcase, for example) is being placed in the sensitive area by a tracked moving object (a person, for example) for the defined debounce time.
   - Taken objects: Generates metadata if an idle object (a suitcase, for example) in the sensitive area is being taken away by a tracked moving object (a person, for example) after the defined debounce time.

4. In the **Debounce time [s]** box, enter the time span in seconds for which an object must remain idle in order to be classed as such.

5. Only for CPP6 and CPP7 cameras:
   - In the **Object area [m²]** box, enter the minimum and maximum size for all objects that will generate an alarm event. Objects that are smaller or larger than the specified sizes will be ignored. Make sure that the range between the minimum and maximum size is not too small, to avoid that relevant objects are unintentionally eliminated from alarm generation.
   - **Note:** The values are graphically displayed in the camera image by two yellow-framed squares. Drag one of the blue nodes to adjust the values. The yellow squares can be moved in the camera image to cover objects being used for size comparison.

See also

- Configuring the Removed object task, page 55
- Configuring the Idle object task, page 57

9.2.6 Configuring the crowd fields

in Configuration Manager: VCA tab > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > Metadata Generation tab > Crowd Fields tab
This page allows you to define crowd fields.

To define crowd fields:

1. On the Crowd Field Settings page, click Add. A crowd field is added to the camera image.
   
   **Note:** You can also define a crowd field directly in the camera image. To do this, click into the camera image. Each click creates a new corner of the crowd field. A double-click closes the crowd field.

2. In the camera image, adjust the position and size of the crowd field if necessary.

To remove crowd fields:

- On the Crowd Field Settings page or in the camera image, select a crowd field, then click Remove.

9.3 Metadata inspection - statistics

The values that are displayed allow you to estimate which minimum and maximum values you must enter for the creation of a task to ensure the desired objects are detected.

To display the statistics:

- Click an object in the camera image.
  
  The object is marked with a yellow flag and the object properties are displayed.
  
  The lines indicate the percentage of objects for which the respective value was detected.
  
  The higher the line, the more objects matched the particular criterion.
  
  The x-axis of the histograms (for example, area and speed) automatically adapts.
  
  The histograms distinguish between objects that trigger an alarm (red line) and those that do not (blue line).
  
  Blue lines: Set of objects with no alarm
  
  Red lines: Set of objects with alarm

**Note:**

- If a marked object leaves the sensitive area, the properties can no longer be monitored.
  
  This also applies to objects that do not move for a longer period of time. The value display no longer changes if this is the case. If necessary, click another object.

- The progression graph displays the change in values of each property during the previous 30 seconds.

- The properties of a moving object are always changing. An automobile does not always drive at a constant speed; a person sits down and stands up or changes direction.

- Colors cannot be detected for very small objects.

- The color of an object depends on the lighting of the image, for example. Different colors are detected under a floodlight than in the shade.

- The color properties of the marked object are displayed using color columns that are arranged according to their weighting. The further to the left a column is, the higher its proportion of the object's color property.

- The color columns are also updated once every second. It changes when the color property of the marked object changes.

- Colors that appear as less than 5% are not displayed.
– Pause the pointer on a color columns, to display a ToolTip with values for hue, saturation and value (HSV), as well as the weighting of the color.

To restart the statistics:
  ▷ Click **Reset**.

**See also**
– *Metadata inspection - statistics, page 33*
10 Configuring Intelligent Video Analytics Flow

This chapter describes the configuration and different settings for Intelligent Video Analytics Flow.

10.1 Configuring tasks

- In Configuration Manager: VCA tab > Profile #1 or Profile #2 and Intelligent Video Analytics Flow > Tasks tab
- In Web browser: Alarm > VCA > Profile #1 or Profile #2 and Intelligent Video Analytics Flow > Configuration button > Tasks tab

A task is always created or edited using a wizard. When you use the wizard to create or edit a task, you have access to the camera image and the commands, for example to create, edit or delete fields. Expert users can adapt tasks to their requirements using VCA Task Script Editor. You can immediately recognize from the color of object outlines whether an object will trigger an alarm with the given settings.

**Notice!**
Before defining tasks, specify the sensitive area and the motion detection parameters.

See also
- Tasks, page 35

10.1.1 Configuring the Detect any flow task

- In Configuration Manager: VCA tab > Profile #1 or Profile #2 and Intelligent Video Analytics Flow > Tasks tab
- In Web browser: Alarm > VCA > Profile #1 or Profile #2 and Intelligent Video Analytics Flow > Configuration button > Tasks tab

When you work with Intelligent Video Analytics Flow for the first time, the default task Detect any flow is already available. This task detects all flows in the entire camera image. Initially, even the global settings are preset in such a way that no object is excluded. This first preset task corresponds in the configuration to the task type Flow in field.

See also
- Configuring the Flow in field task, page 77

10.1.2 Configuring the Tampering task

- In Configuration Manager: VCA tab > Profile #1 or Profile #2 and Intelligent Video Analytics Flow > Tasks tab
- In Web browser: Alarm > VCA > Profile #1 or Profile #2 and Intelligent Video Analytics Flow > Configuration button > Tasks tab

This task generates an alarm event if it must be assumed that the video source (camera) has been tampered with. Here, you can only activate the filter for the relevant events. You cannot alter the settings for tamper detection. Only the settings selected on the VCA start page can be activated here.

To select the task:
2. On the Create a Task page, select Tampering, then click OK.

Define the Trigger page
One of the activated events must occur to trigger an alarm event.
Select the corresponding event.

**Scene too bright**
Tampering associated with exposure to extreme light (for instance, shining a flashlight directly on the lens) should trigger an alarm. The average brightness of the scene provides a basis for recognition.

**Scene too dark**
Tampering associated with covering the lens should trigger an alarm. The average brightness of the scene provides a basis for recognition.

**Reference check**
A deviation from the reference image on the VCA start page should trigger an alarm.

### 10.1.3 Configuring the Crowd detection task

- **In Configuration Manager:** VCA tab > Profile #1 or Profile #2 and Intelligent Video Analytics Flow > Tasks tab
- **In Web browser:** Alarm > VCA > Profile #1 or Profile #2 and Intelligent Video Analytics or Essential Video Analytics > Configuration button > Tasks tab

This task generates an alarm event if a number of objects are located within a certain area. The area is defined by a crowd field in the camera image.

To use the **Crowd detection** functionality, first create a reference image of the background without people present on the standard VCA configuration page. The reference image must depict the current background captured by the camera. Create a new reference picture if the background has changed.

To select the task:
1. On the **Surveillance Tasks** page, click New.
2. On the **Create a Task** page, select Crowd detection, then click OK.

**Filter by Crowd Field Properties page**

1. In the **Select a crowd field:** list, select one of the crowd fields that have already been created.
   
   **Note:** You cannot create or edit a crowd field here.

2. Move the **Crowd density** slider to define how dense a crowd must be to be detected as a crowd.
   
   The equivalent on the scale is different according to the settings and conditions of each system. Determine a meaningful threshold value for triggering an alarm for your setup by testing.

3. In the **Debounce time [s]** box, enter the minimum time that a crowd must be detected within the field before it triggers an alarm

4. In the **Smoothing time [s]** box, enter the minimum time after which an alarm is triggered if the average crowd density over this period exceeds the value set by the Crowd density slider.

**See also**
- Configuring the crowd fields, page 80

### 10.1.4 Configuring the Flow in field task

- **In Configuration Manager:** VCA tab > Profile #1 or Profile #2 and Intelligent Video Analytics Flow > Tasks tab
- **In Web browser:** Alarm > VCA > Profile #1 or Profile #2 and Intelligent Video Analytics Flow > Configuration button > Tasks tab

This task generates an alarm event if a flow (overall movement) is detected within a certain area. The area is defined by a field in the camera image.
To select the task:

1. On the **Surveillance Tasks** page, click **New**.
   - On the **Create a Task** page, select **Flow in field**, then click **OK**.

**Define the Field page**

1. Select a field from the list or create a new one.
   - To create a new field, click into the camera image to start with the first corner of the field, then click again for each corner. Finish the field by double-clicking.
   - **Note:** You can also select **Whole screen** or edit an existing field.

2. In the **Debounce time [s]** box, enter the minimum time a flow must be detected within the field before an alarm event will be triggered.

**Filter by Flow Properties page**

Limit the properties of a flow that triggers an alarm event. Flows that do not correspond to the properties specified here do not trigger an alarm event.

1. Select the **Direction 1 [°] / Direction 2 [°]** check boxes.

2. In the **Direction 1 [°] / Direction 2 [°]** boxes, enter a minimum and a maximum value (angle) to define the directions. Only flows moving in these directions will trigger an alarm event.
   - The directions are displayed as yellow circle segments in the camera image.
   - You can also define the direction as follows:
     - Place the pointer in the yellow circle segment, press and hold the mouse button, then turn the segment.
     - Place the pointer over one of the edges of the yellow circle segment, press and hold the mouse button, then move the edge.

3. Select the **Activity [% of area]** check box if you wish to filter flows that should trigger an alarm event based on their activity.
   - In this context, an activity is the percentage of the monitored area in which a flow is detected.

4. In the **Activity [% of area]** boxes, enter a minimum and a maximum value for the activity.
   - The selected values are displayed on the camera image during input by a respectively high number of yellow dots. The number of arrows indicating the detected flow is directly proportional to the activity in the area.

5. Select the **Speed** check box, if you wish to filter flows that should trigger an alarm event based on their speed.

6. Select the lowest and highest speed.
   - The selected speeds are indicated by two moving dots on the camera image.
   - **Note:** You can move or rotate this field using the pointer. Place it over an area with a flow. This will enable you to align the flow speed with the selected settings.

**See also**

- **Fields, page 35**

### 10.1.5 Configuring the Counterflow in field task

- ■□□ in Configuration Manager: **VCA** tab > **Profile #1** or **Profile #2** and Intelligent Video Analytics Flow > **Tasks** tab

- ■■□□ in Web browser: **Alarm** > **VCA** > **Profile #1** or **Profile #2** and Intelligent Video Analytics Flow > **Configuration** button > **Tasks** tab

This task generates an alarm event if a flow moving against a main flow is detected within a certain area.

To select the task:
1. On the **Surveillance Tasks** page, click **New**.
   - On the **Create a Task** page, select **Counterflow in field**, then click **OK**.

**Define the Field page**

1. Select a field from the list or create a new one.
   - To create a new field, click into the camera image to start with the first corner of the field, then click again for each corner. Finish the field by double-clicking.
   
   **Note:** You can also select **Whole screen** or edit an existing field.

2. In the **Debounce time [s]** box, enter the minimum time a flow must be detected within the field before an alarm event will be triggered.

**Filter by Counterflow Properties page**

1. In the **Angle of tolerance for counterflow [°]**: box, enter the value for the maximum deviation of the counterflow against the main flow. Angles between 0° and 180° are valid.
   
   **Note:**
   The general direction of motion is automatically recognized as the main flow. Only flows moving in the opposite direction – taking into account the deviation -will trigger an alarm event.

   By selecting 0°, the direction of motion is restricted in such a way that any counterflow will not be detected, while selecting 180° will ensure that every movement is detected.

2. In the **Adaption time window [s]**: box, enter the period during which there must be activity for a main flow to be detected. As soon as a main flow is detected as such, the counterflow will also be detected.

3. Select the **Activity [% of area]** check box if you wish to filter flows that should trigger an alarm event based on their activity.
   
   In this context, an activity is the percentage of the monitored area in which a flow is detected.

4. In the **Activity [% of area]** boxes, enter a minimum and a maximum value for the activity.
   The selected values are displayed on the camera image during input by a respectively high number of yellow dots. The number of arrows indicating the detected flow is directly proportional to the activity in the area.

5. Select the **Speed** check box, if you wish to filter flows that should trigger an alarm event based on their speed.

6. Select the lowest and highest speed.
   
   The selected speeds are indicated by two moving dots on the camera image.
   
   **Note:** You can move or rotate this field using the pointer. Place it over an area with a flow. This will enable you to align the flow speed with the selected settings.

**See also**

- **Fields**, page 35

### 10.2 Metadata generation

**Notice!**

This tab provides access to basic settings that you can adapt for performance optimization. The settings and values defined here are valid for all tasks.

#### 10.2.1 Configuring the sensitive area

In Configuration Manager: VCA tab > **Profile #1** or **Profile #2** and Intelligent Video Analytics Flow > **Metadata Generation** tab > **Sensitivity Settings** tab
To define insensitive areas:

1. On the VCA Masking page, click Add. An insensitive area is added to the camera image.
   
   Note: You can also define an insensitive area directly in the camera image. To do this, click into the camera image. Each click creates a new corner of the insensitive area. A double-click closes the insensitive area.

2. In the camera image, adjust the position and size of the insensitive area if necessary.

3. Move the Tracking sensitivity slider and set the sensitivity:
   
   Min.: This setting is useful in simple environments in which objects move in a straight line and are not hidden during their motion through the area concerned.
   
   Max.: Even minor activities are detected. This setting is useful if the camera has a small tilt angle and in environments in which objects are often hidden. However, this setting may mean that camera noises (especially in low-visibility conditions) are also detected as motion.

4. Select the Min. tracking duration [s] check box and enter the period for an object to be detected. Select the check box to detect slow objects.

5. Select the Min. tracking distance check box and enter the distance an object must cover to be detected. Select the check box to detect quick objects.

To remove insensitive areas:

1. On the VCA Masking page, select an insensitive area from the list or in the camera image, then click Remove.

See also

– Sensitive area, page 36

10.2.2 Configuring the crowd fields

To define crowd fields:

1. On the Crowd Field Settings page, click Add. A crowd field is added to the camera image.
   
   Note: You can also define a crowd field directly in the camera image. To do this, click into the camera image. Each click creates a new corner of the crowd field. A double-click closes the crowd field.

2. In the camera image, adjust the position and size of the crowd field if necessary.

To remove crowd fields:

1. On the Crowd Field Settings page or in the camera image, select a crowd field, then click Remove.

10.3 Metadata inspection – statistics

The values that are displayed allows you to estimate which minimum and maximum values you must enter for the creation of a task to ensure the desired flow is detected. Furthermore, the values help you to check and refine the filter criteria for flows.

To display the statistics:
Click an object in the camera image. The lines indicate the percentage of flows for which the respective value was detected. The higher the line, the more flows matched the particular criterion. The histograms distinguish between flows that trigger an alarm (red line) and those that do not (blue line).

Blue lines: Set of flows with no alarm
Red lines: Set of flows with alarm

To restart the statistics:
- Click Reset.

- Metadata inspection - statistics, page 37
11 Configuring MOTION+

This chapter describes the configuration and different settings for MOTION+.

11.1 Configuring tasks - general

**in Configuration Manager:** VCA tab > Profile #1 or Profile #2 and MOTION+ > Tasks tab

**in Web browser:** Alarm > VCA > Profile #1 or Profile #2 and MOTION+ > Configuration button > Tasks tab

A task is always created or edited using a wizard. When you use the wizard to create or edit a task, you have access to the camera image and the commands, for example to create, edit or delete fields. Expert users can adapt tasks to their requirements using VCA Task Script Editor. You can immediately recognize from the color of object outlines whether an object will trigger an alarm with the given settings.

11.1.1 Configuring the Detect any motion task

**in Configuration Manager:** VCA tab > Profile #1 or Profile #2 and MOTION+ > Tasks tab

**in Web browser:** Alarm > VCA > Profile #1 or Profile #2 and MOTION+ > Configuration button > Tasks tab

When you work with MOTION+ for the first time, the default task Detect any motion is already available. This task detects all moving objects in the entire camera image. Initially, even the global settings are preset in such a way that no object is excluded. This first preset task corresponds in the configuration to the task type Motion in field.

11.1.2 Configuring the Motion in field task

**in Configuration Manager:** VCA tab > Profile #1 or Profile #2 and MOTION+ > Tasks tab

**in Web browser:** Alarm > VCA > Profile #1 or Profile #2 and MOTION+ > Configuration button > Tasks tab

This task generates an alarm event if an object moves within a certain area. The area is defined by a field in the camera image.

To select the task:
2. On the Create a Task page, select Motion in field, then click OK.
3. In the Task name: box, enter the name of the task.

**Define the Field page**

1. Select a field from the list or create a new one.
   - To create a new field, click into the camera image to start with the first corner of the field, then click again for each corner. Finish the field by double-clicking.
   - **Note:** You can also select Whole screen or edit an existing field.
2. In the Debounce time [s] box, enter the minimum time that an object must remain within the field before it triggers an alarm. To do this, select the field in the camera image first, then enter the value. If necessary, enter the time for each field.
   - **Note:** By entering a value, you can prevent the triggering of multiple alarm events by objects that are constantly moving toward and away from the boundary of the field.
Filter by Motion Properties page

1. Select the **Activity [% of area]** check box if you wish to filter motion that should trigger an alarm event based on their activity. This allows you to set a minimum amount of independent and possibly unconnected detection blocks in the field that have to indicate changes.

   In this context, an activity is the percentage of the monitored area of the camera in which motion is detected.

2. In the **Activity [% of area]** boxes, enter a minimum and a maximum value for the activity. The selected values are displayed in the monitored area of the camera image during input by a respectively high number of yellow dots.

3. Select the **Size of cell cluster [% of whole screen]** check box if you wish to filter motion that should trigger an alarm event based on their size.

4. In the **Size of cell cluster [% of whole screen]** boxes, enter the minimum and maximum size of the cell clusters in percentage based on the whole screen.

   The minimum value is displayed in the camera image during the input by a yellow shaded rectangle, the maximum value by a yellow frame.

- **Field**, page 38

### 11.2 Metadata generation

**Notice!**

This tab provides access to basic settings that you can adapt for performance optimization. The settings and values defined here are valid for all tasks.

#### 11.2.1 Configuring the sensitive area

- in Configuration Manager: **VCA** tab > **Profile #1** or **Profile #2** and **Intelligent Video Analytics** or **Essential Video Analytics** > **Metadata Generation** tab > **Sensitive Area** tab

- in Web browser: **Alarm** > **VCA** > **Profile #1** or **Profile #2** and **Intelligent Video Analytics** or **Essential Video Analytics** > **Configuration** button > **Metadata Generation** tab > **Sensitive Area** tab

This page allows you to define insensitive areas.

To define insensitive areas:

1. On the **VCA Masking** page, click **Add**. An insensitive area is added to the camera image. **Note:** You can also define an insensitive area directly in the camera image. To do this, click into the camera image. Each click creates a new corner of the insensitive area. A double-click closes the insensitive area.

2. In the camera image, adjust the position and size of the insensitive area if necessary.

3. Move the **Sensitivity** slider and set the sensitivity:
   - **Min.**: Even minor activities are detected. This setting is useful if the camera has a small tilt angle and in environments in which objects are often hidden. However, this setting may mean that camera noises (especially in low-visibility conditions) are also detected as motion.
   - **Max.**: This setting is useful in simple environments in which objects move in a straight line and are not hidden during their motion through the area concerned.

To remove insensitive areas:

- On the **VCA Masking** page, select an insensitive area from the list or in the camera image, then click **Remove**.
See also
- Sensitive Area, page 39

11.3 Metadata inspection

The values that are displayed allow you to estimate which minimum and maximum values you must enter for the creation of a task to ensure the desired objects are detected.

See also
- Metadata inspection – statistics, page 40
12 Configuring Tamper detection

- In Configuration Manager: VCA tab > Tamper Detection tab
- In Web browser: Alarm > VCA

This functionality allows you to detect tampering of cameras and video cables by means of various options. Run a series of tests at different times of the day and night to ensure that the video sensor is operating as intended.

To configure tamper detection:

1. Click Reference to save the currently visible video image as a reference.
2. Click Mask... The reference image is displayed in a new pane.
3. Click Add mask. A black square (mask) is displayed as default.
   Note: The area inside the mask is excluded from monitoring.
4. Define the areas that are excluded from monitoring.
   To do this, edit the mask and drag it to the correct position in the reference image.
   - To change the mask size:
     Select the mask, and then drag the line or the corners (nodes) of the mask to the desired position in the camera image.
   - To move the mask:
     Select the mask, and then drag the field as a whole to the desired position in the camera image.
   - To insert a corner (node):
     Select the mask, and then double-click a line.
   - To delete a corner (node):
     Select the mask, and then double-click a corner.
   - To delete a mask:
     Select the mask, and then click Delete mask.
5. Select the Reference check check box to activate the on-going check. The stored reference image with the excluded areas is displayed below the current video image.
6. Move the Sensitivity slider to the left to decrease the sensitivity or move the slider to the right to increase the sensitivity.
   Note: The basic sensitivity of the tamper detection can be adjusted for the environmental conditions to which the camera is subject. The algorithm reacts to the differences between the reference image and the current video image. The darker the observation area, the higher the value that must be selected.
7. Move the Trigger delay [s] slider to the left to decrease the delay or move the slider to the right to increase the delay.
   Note: Set delayed alarm triggering here. The alarm is only triggered after a set time interval in seconds has elapsed and then only if the triggering condition still exists. If the original condition has been restored before this time interval elapses, the alarm is not triggered. This avoids false alarms triggered by short-term changes, for example, cleaning activities in the direct field of vision of the camera.
8. Select the Disappearing edges or Appearing edges option to specify the reference check once again.
   - Disappearing edges
     The area selected in the reference image should contain a prominent structure. If this structure is concealed or moved, the reference check triggers an alarm. If the selected area is too homogenous, so that concealing and moving the structure would not trigger an alarm, then an alarm is triggered immediately to indicate the inadequate reference image.
   - Appearing edges
Select this option if the selected area of the reference image includes a largely homogenous surface. If structures appear in this area, then an alarm is triggered.

9. Select the **Global change** check box if a global change in the video image, as set with the **Global change** slider, should trigger an alarm.

10. Move the **Global change** slider to set how large the global change in the video image must be for an alarm to be triggered. This setting is independent of the sensor fields selected under **Mask...**. Set a high value if fewer sensor fields need to change to trigger an alarm. With a low value, it is necessary for changes to occur simultaneously in a large number of sensor fields to trigger an alarm.

11. Select the **Scene too bright** check box if too bright light conditions should trigger an alarm.

12. Move **Threshold** the slider to the desired position. The value is displayed to the right of the slider.

13. Select the **Scene too dark** check box if you want to detect camera covering, for example.

14. Move **Threshold** the slider to the desired position. The value is displayed to the right of the slider.
13 **Using AUTODOME and MIC cameras**

If you implement Intelligent Video Analytics or Intelligent Video Analytics Flow with AUTODOME and MIC cameras, please note the following:

- There are 16 different profiles available for configuring Intelligent Video Analytics. Each profile can be assigned to a different preset. Each preset can have its own Intelligent Video Analytics configuration. Define the camera positions for the individual presets before starting to configure Intelligent Video Analytics.

- Once you have assigned the Intelligent Video Analytics profile to a preset, the AUTODOME camera is blocked to other users for approximately ten minutes.

- An Intelligent Video Analytics image data analysis is launched approximately two seconds after the AUTODOME camera has recalled a preset. It is irrelevant whether this is part of a tour or whether it is completed manually. When presets are recalled as part of a tour, the minimum dwell period for a preset should not be below ten seconds; it should be at least one minute.

- As soon as the AUTODOME camera is moved to a new position or the zoom, iris or focus settings are changed, Intelligent Video Analytics is no longer active for this scene.

- As soon as a message from the AUTODOME camera is displayed on the camera image, Intelligent Video Analytics is no longer active for this preset. Recall this preset to reactivate Intelligent Video Analytics for this scene.

- Use the **Inactivity** function to ensure that the camera automatically recalls a preset when it becomes inactive. This is particularly important for AUTODOME cameras where the images are not viewed immediately. For more information, refer to the camera documentation.

- Some of the AUTODOME cameras will enable you to reuse an alarm event triggered by Intelligent Video Analytics as an alarm input. Thus, for example, an event detected on preset 1 can cause the recall of another preset.
Glossary

**camera calibration**

Teaching a camera about its field of view and perspective to obtain 3D metric information from a 2D camera image.

**condition**

A restriction of an alarm or statistic task to objects of certain properties, for example, object type, area, speed and direction.

**field**

A polygon created by the user that specifies a certain area within a camera image, for example, an entrance or the open space in front of a barrier.

**line**

A thin mark within a camera image created by the user that contains a starting point and endpoint. A line can consist of several segments.

**loitering**

The process of an object staying in a certain area for a specified period of time. The object can either standing still or moving around.

**object**

Typically people or vehicles moving within the area seen by the camera.

**object classification**

Assignment of object types (person, car, bike, truck or unknown) to tracked objects.

**route**

A path within a camera image that an object must follow more or less closely to trigger an alarm.

**sensitive area**

That part of the camera image where motion can be detected.

**task**

The description of spatial, temporal and other object properties that need to be met to trigger an alarm or to update a statistic.
